used to illustrate the divergency between globally optimal emission reductions and the emission reductions chosen by individual countries striving to maximize the welfare of their respective citizens. In this context, it is sufficient to interpret the curves in Fig. 1 to be the best estimate of the relationships dealt with here that is available to the political decision-makers. Of course, a benefit curve like the one that has been drawn for country i can be drawn for any other country. This is not done in the figure. However, a curve $B^{\Sigma}(X_i)$ is drawn representing the vertical aggregation of the individual benefit curves of all countries. This aggregate curve shows how the sum of worldwide benefits from pollution reduction depends upon emissions reduction of country i . Additionally, Fig. 1 presents the curve $C_i(X_i)$ representing how the costs of emission reduction in country i depend upon the quantity of emissions that this country reduces. Comparing these curves, it is obvious that the globally optimal level of GHG reductions in country i is at X_i^{**} , the quantity where the difference between the aggregate benefit curve and the curve representing the abatement cost of country i is maximized. The quantity of emission reductions maximizing the welfare in country i (the “equilibrium quantity” for country i), however, is at X_i^* . In addition to these curves representing total benefits and costs, the figure shows the curves $MB_i(X_i)$, $MB^{\Sigma}(X_i)$, $MC_i(X_i)$. These curves are “partner curves” to the aforementioned curves in that they represent the marginal country-specific benefits, marginal aggregate benefits, and marginal country-specific costs instead of the total benefits and costs. These curves represent the country-specific benefits, aggregate benefits, and country-specific costs, respectively, for small increases of the quantity of emissions reduced. Technically speaking, these marginal curves are the first-order derivatives of the total curves. The equilibrium emission reduction quantity, X_i^* , for country i is defined by the intersection of the country’s specific marginal benefit curve with the country’s specific marginal cost curve. For any quantity lower than X_i^* , the marginal benefit of the last unit’s reduction is higher than the cost of this last unit. Therefore, national welfare could be increased by reducing

an additional unit. It follows that the starting point emission reduction level in this little thought experiment cannot be the equilibrium one. Analogously, for any level of pollution abatement beyond X_i^* , it can be argued that national welfare increases when pollution abatement is attenuated. By analogous reasoning, it can be shown that the globally optimal quantity of emission reduction, X_i^{**} , is defined by the intersection of the marginal aggregate benefit curve, $MB^{\Sigma}(X_i)$, and the marginal country-specific cost curve, $MC_i(X_i)$. In economic analysis (as applied to environmental problems and very many other issues), marginal analysis is a very common and powerful tool. It will be repeatedly used in a subsequent exposition.

International Environmental Agreements – Painful Genesis and Fragile Architecture

In the preceding section, the decisions of national governments have been stylized regarding the quantity of GHG reductions. It has been shown that a national GHG policy striving to maximize national welfare is unable to meet the global requirements of effective GHG reduction.

Even though we obviously do not have a “world government,” it is instructive to imagine what a government like that might do. The result of this reasoning may be used as a benchmark which serves for the results of real world decision processes. To build up this benchmark, it is usually assumed in economics that this world government is well informed and benevolent. Applying the established economic welfare criteria, the world government would choose a situation with two essential properties. The first property is that GHG emissions would be at their globally optimal level as characterized in the preceding section. The second property relates to the question, how much each individual country would have to contribute to the globally optimal aggregate emission reduction. Thriving to keep the worldwide total costs of GHG abatement at their minimum, the world government would put a burden to an individual country which would be

the higher, the lower the abatement cost of this country is. More precisely, the cost-effective distribution of country-specific emission reduction loads is characterized by the marginal abatement costs to be equal across all countries. This “equi-marginal condition” is very often used in economics (within the environmental context and beyond) and is explained more elaborately, e.g., in Endres (2011), pp. 216–220. If the countries of the world are aware of what has just been said and note that this solution cannot be achieved by country-specific “autistic” welfare maximization, they might try to get there by *voluntary agreement*.

The fundamental challenge to the design of international agreements to fight global warming is that they must be *self-enforcing* since international law is too weak to implement enforcement. This means that the international contract must be designed in a manner that it is attractive for each country to join in, and having joined, to keep the commitments. These two properties are called the *individual rationality* and the *stability* of an international treaty.

Very unfortunately, it does not follow from the global optimality property of an international GHG treaty that it is also individually rational and stable. To the contrary, for many countries there is an incentive to “cheat” upon the commitments they have signed in an international agreement by taking a *free ride* on the GHG abatement efforts of the other partaking countries (lacking stability). Moreover, some countries might have an incentive not to sign the treaty at all, even though this treaty is optimal from the global point of view (lacking individual rationality). This is particularly so for countries with low marginal abatement costs which do not suffer very much from global warming (or may even benefit from it).

There are many attempts in the literature to fill these rather theoretical considerations with empirical content. A prominent example is a study by Finus/van Ierland/Dellink (2006). (There is a textbook-style interpretation of the aforementioned original research in Endres (2011).) To investigate the incentive compatibility of a globally optimal GHG agreement, the authors of this study proceed as follows. They divide the world

into 12 “regions” and use data from the empirical literature to estimate the GHG abatement benefit and cost functions for each of those regions. These 12 regions (countries or groups of countries, respectively) are USA, Japan, European Union, other OECD countries, Central and Eastern European countries, former Soviet Union, energy-exporting countries, China, India, dynamic Asian economies, Brazil, and “rest of the world”. The result in terms of individual rationality is that three regions would deteriorate their welfare position when the situation would change from the pre-treaty situation (with each country maximizing its own welfare “autistically”) to the globally optimal contract. These regions are the “other OECD countries,” the “Central and Eastern European countries,” and the countries of the former Soviet Union. For these, it is not individually rational to join a coalition that agrees to realize the globally optimal global warming policy. The results of the stability test are even less encouraging: With the exception of the European Union and Japan, all regions are subject to an incentive to leave a coalition that has agreed upon the globally optimal GHG abatement policy. Of course, there are very many uncertainties regarding the physical and economic aspects of GHG emission and global warming. Therefore, the specific numbers of this study quantifying the costs and benefits of GHG abatement in the 12 regions cannot be really taken for granted (as the authors of this study are well aware of and concede). Still, the study illustrates the fundamental difficulties that impede the international coordination of an effective policy to fight global warming. This study (and other empirical treatments) is able to explain why the *Kyoto Protocol* suffers from so many weaknesses and why it is so difficult to agree upon an effective succeeding treaty.

In the preceding analysis, it has been shown that it is extremely difficult for sovereign countries to agree upon a globally optimally designed global warming treaty and to enforce it. Obviously, the globally optimal contract is a very ambitious goal. Thus, the question arises whether the international legislation process has better expectations if it strives for a somewhat more pragmatic goal. A pragmatic program

might seek to curb climate change such that the adverse consequences are “tolerable” and allocate the abatement costs among the countries in an “acceptable” way. It has been shown in an extensive literature that this change in the scenario does not lighten up the situation dramatically (See Finus/Caparrós (2015) and Finus/Rundshagen (2015) for fundamental issues and recent developments.). Incentive compatible international global warming agreements are likely to be either deep (ambitious reduction target) or wide (high participation rate of countries) and very unlikely to be both.

Leakage

Let us assume that a country or a group of countries, against all odds, would decide to take serious national measures to reduce GHG emission and then fully enforce these measures.

The country or the group of country could take a number of steps that would aim at reducing energy consumption and especially at replacing fossil energy sources with regenerative ones. However, these activities would result in a lower demand of fossil energy sources and thus, *ceteris paribus*, in a downward pressure on the prices. The decreasing world market prices would stimulate the demand of fossil energy sources in other countries. There, the increasing usage of these energy sources would, *ceteris paribus*, lead to a rise of the relevant emission though. This interdependence is called “leakage effect” in economics. It results in the dissipation of the self-limiting activities of pioneer countries. If this effect is anticipated, even the countries that would agree to limit themselves would be less willing to do so than without the leakage effect.

This reasoning can be illustrated by Fig. 2. The abscissa shows the stock of a fossil energy resource R fixed at a level of $\bar{R}$. There are two groups of countries in the stylized cosmos of this illustration, green countries (G) and nongreen countries (NG). The green countries are the ones mentioned in the introductory paragraph of this section. They take effective GHG curbing measures. In the pre-policy situation (the time before

Global Warming, Fig. 2 Leakage in the Resource Market

the green countries decide and act upon their measures), the demand curves for the fossil energy resource are D_{GI} for the green countries and D_{NG} for the nongreen ones. The market equilibrium price (P_I) and the market equilibrium distribution of the resource stock between the two countries $(R_G, R_{NG})_I$ are defined by the intersection of these two demand curves. The effect of the GHG-fighting policy in the green countries is that their demand for the fossil resource is reduced. In the figure, this is illustrated by the demand curve of the green countries shifting down from D_{GI} to D_{GII} . Accordingly, the market equilibrium shifts from A to B in the figure. In detail, that means that the equilibrium price goes down from P_I to P_{II} and the equilibrium distribution of the resource between the two groups of countries changes from $(R_G, R_{NG})_I$ to $(R_G, R_{NG})_{II}$. In terms of global warming, the result of this analysis is that total consumption of the fossil resource is unaffected by the efforts of the green countries. Thereby, GHG emissions jointly produced with the consumption of this resource are unchanged. The GHG emission “savings” generated by the policy of the green countries are completely used up by the additional consumption of the nongreen countries.

Of course, this is a very stylized reasoning which might not completely cover what is happening in the real world. But, it still illustrates the

“curse of partial solutions” to the global warming problem.

Moreover, the case in which the leakage effect is “transported” via the market for the resource is only one of several forms this detrimental effect might take on. Other forms are discussed in the literature, e.g., in Rauscher/Lünenbürger (2004).

The Dilemma of Intergenerational Allocation

In the preceding analysis, incentive problems of effective global warming policy have been discussed in a framework focusing on the present generation. However, there is also an intergenerational dilemma of global warming policy. GHG reductions conducted in the present are beneficial not only presently but also for future generations. Thereby, an intertemporal externality is generated. The allocative consequences of this externality are analogous to what has been said in the intragenerational context above: Equilibrium GHG reductions of the present generation are too low compared to globally optimal GHG reductions. In the present context, the “global optimality” must be interpreted to comprise the costs and benefits of GHG reduction in all generations. It is plausible without further elaboration that this intertemporal misallocation occurs if the present generation is oblivious with respect to the welfare of future generations. It may come as a surprise, however, that the intergenerational allocation problem does not vanish even if we assume that the preferences of the present generation are not so self-centered. Let us assume the opposite and take the present generation to be *future-altruistic* in the sense that it takes the welfare of future generations into account during its decision-making processes just as it takes its own welfare into account.

To see the point, let us look again at a single country. If a single country trying to optimize the situation for its own citizens and their descendants decides to use less fossil energy, it preserves the energy resources of mankind and causes less CO₂ emissions. However, it cannot be sure that the aforementioned “target group” will benefit from

this saving. It must rather anticipate that the saved resources will be consumed by its contemporaries in the other countries. As far as this does not happen, it is by no means granted that the descendants of the country under consideration will benefit from the savings. Instead, the future generations of another country might consume the resources saved by the country under consideration. By this, the aforementioned leakage effect gets a time dimension. Thus, the incentive to save resources is limited for a country that acts “selectively altruistic” insofar that it only cares for its own children and children’s children. This incentive distortion can be compared to the one, where individual self-restraint collapses due to the exploitation of *open access resources*. So the individual fisherman does not heed the advice he should bear in mind that he wants to go fishing again tomorrow: The decision-maker knows that present consumers (and, if anything is left, future consumers) will profit from his self-restraint and his own provision will suffer. This results in a phenomenon well known from the economics of natural resources, namely, the individually rational, but collectively unreasonable depletion of freely accessible fishing resources.

Now let us assume (neglecting any concerns based on economic theory) that not a single country would act future-altruistically but the worldwide population as a whole would seriously think about it. Unfortunately, even such an assumption cannot solve the intertemporal incentive problem sufficiently. The trouble is that a present generation, even if it comprises the whole earth, can never be sure whether the succession of coming generations might benefit from a better world climate because of their self-restraint regarding the consumption of natural resources. It is already the very next generation that is tempted to exploit the resources the present generation has left them and to waste them regardless of the CO₂ emissions. Since the generations are naturally limited to a certain period of time, there is nothing generation 1 can do to protect their future-altruistic sacrifices from the exploitation of generation 2. This *constitutional nonprotection* of investments intended to support coming generations is a substantial obstacle for making the investments

at all. The incentive structure for the present generation is discouraging and can be compared to an investor who thinks about getting economically engaged in a politically unstable country. Since he cannot be sure of how long his investments will be profitable, he is subject to an incentive not to invest at all or only in projects that might be profitable in the short run. Climate protection is a *very* long-term project, though.

The Dismal Science and Its Strive for Climate Change Optimism

Economics is often called the *dismal science*. The pessimistic assessment of the expectations to curb global warming by international GHG policy, as given above, is an obvious tribute to this trademark. However, there are also some strands of economic thinking which might be able to lighten up the picture. Two important examples are *technical change* and *adaptation*.

In the preceding analysis, it has been tacitly assumed that the costs to reduce GHG emissions are given in the sense that they do not change over time. More precisely (and technically speaking), the cost functions mapping alternative quantities of GHG abatement into alternative amounts of cost are invariant. Therefore, in Fig. 1, above, there is only one marginal cost function. This representation is no longer appropriate if we allow for technical change. An important form of this change may be stylized in that with a superior technology more greenhouse gases can be reduced at a given cost than using old-fashioned technology. An equivalent understanding is that a given quantity of greenhouse gases can be reduced at lower cost using the new technology compared to using the old one. In the language of Fig. 1, this kind of technical progress makes the marginal cost curve go down. We illustrate this change in Fig. 3 denoting the marginal cost function, which is valid if the old technology is used, $MC_i^{(1)}$. Accordingly, the cost function illustrating economic circumstances if the new technology is used is called $MC_i^{(2)}$.

It is plausible that technological change making GHG reduction cheaper tilts the scale of

Global Warming, Fig. 3 GHG Abatement and Technical Change

national decision-making into the direction of reducing more greenhouse gases with the new technology than with the old one. In Fig. 3, this is illustrated in that the equilibrium reduction quantity for country i increases from $X_i^{*(1)}$ to $X_i^{*(2)}$. From the perspective of economic theory, this does not reduce the size of the misallocation, since not only the equilibrium quantity increases due to technical change but also the globally optimal quantity. The latter quantity increases from $X_i^{**(1)}$ to $X_i^{**(2)}$. From an ecological perspective, however, technical change is still improving the situation because the higher GHG reduction quantity contributes to mitigate the global warming problem. To illustrate, imagine a GHG abatement target $\bar{X}_i$ which is extra-economically motivated. Then it is possible (and implied in how the level of $\bar{X}_i$ is entered in Fig. 3) that the equilibrium abatement quantity of country i which is valid for the old technology falls short of this extra-economically determined goal, but the equilibrium quantity which holds for the new technology exceeds this goal. Technically speaking, $X_i^{*(1)} < \bar{X}_i < X_i^{*(2)}$ applies.

Another important issue modifying the fundamental analysis presented in sections I–V above is greenhouse gas adaptation. The idea is that the damage associated with a given level of GHG

emissions (a given level of average world temperature increase) is not given, as has been tacitly implied in the preceding analysis. To the contrary, human decision-makers might attenuate the detrimental effects of climate change by prudently adapting to this change. One of many examples is agriculture. The detrimental effect of an increase in the average temperature is reduced (and might even turn to be negative) if the portfolio of crops grown in a certain region is “reoptimized” in the sense that it is adjusted to the changed climate circumstances. Obviously, this is a completely different approach to global warming than that which has been followed in the earlier sections of this essay. Instead of trying to put a break onto the extent (and speed) of climate change, the issue of adaptation is to try to cope with given climate change as well as possible. Of course, the two approaches may be combined.

If, by successful adaptation, the damage of increasing global temperature is reduced so is the benefit of GHG abatement. In terms of the graphical illustrations that have been used above, the benefit curves shift downwards. In Fig. 4, the marginal benefit curves indexed “(1)” denote the situation without adaptation, and the curves indexed “(2)” show the benefits which occur if adaptation is applied. As the curves are drawn in Fig. 4, equilibrium GHG abatement for country i

goes down from $X_i^{*(1)}$ to $X_i^{*(2)}$ in the process of adaptation. Globally optimal GHG reduction goes down from $X_i^{**(1)}$ to $X_i^{**(2)}$.

So it is plausible (but very well worth noting because often overlooked in the public discussion) that successful adaptation to climate change attenuates the incentive for GHG mitigation. This is not to be regretted if global welfare maximization is the relevant policy goal. Since adaptation makes global warming less harmful, it is to be welcomed that adaptation tilts the scale of GHG policy decision-making into the direction of less GHG abatement. However, there is a dangerous element in that. This is revealed if we turn from global welfare maximization as a policy goal to the aforementioned goal of achieving an extra-economically motivated standard of GHG abatement. To illustrate this, let $\bar{X}_i$ represent this kind of a standard and assume that $\bar{X}_i$ is “located” between the equilibrium reduction quantity of country i without adaptation, $X_i^{*(1)}$, and the equilibrium quantity with adaptation, $X_i^{*(2)}$. Given these relationships, $X_i^{*(1)} > \bar{X}_i > X_i^{*(2)}$, then adaptation induces policy changes which lead to the result that the extra-economically determined standard is missed. Ironically speaking, one might add: it turns out to be very difficult to take the “dismal” out of the dismal science.

Definition

Globalization is the ongoing process of increasing interconnectedness between cross-boundary actors, driven by flows of people, ideas, goods, and capital. Globalization reduces the relevance of these national boundaries and stimulates the emergence of complex networks that foster the exchange and integration of technologies, economies, governance, communities, and culture.

Introduction

In this contribution, we first define and conceptualize globalization by distinguishing between de

jure and de facto forms of globalization and by highlighting its main dimensions. From this conceptualization, we then derive and discuss how we can and are measuring globalization, again in its crucial dimensions; using these measures, we analyze and discuss how globalization has evolved over time and across countries or country groupings. We then look at the consequences of globalization and ways to govern it, from the perspective of three complementary perspectives, the market-centered, state-centered, and people-centered perspectives.

Conceptualizing Globalization

De Jure and De Facto Globalization

An important additional distinction to make both conceptually and empirically is the distinction between de jure and de facto globalization (see e.g., Kose et al. 2009). De jure globalization is expressed in the legal sphere and can be measured through the intensity of regulations, restrictions, and controls on, for example, international trade, capital flows, communications, or the ratification of international treaties. De facto globalization on the other hand measures the actual flows of knowledge, ideas, goods, and people. Both concepts are not necessarily high correlates of each other as high de jure globalization does not automatically lead to high de facto globalization. In certain instances, deliberate repression of de jure globalization may still lead to observed de facto globalization, as ways to circumvent legal restrictions can be found. In the same way does an environment with relatively low de jure restrictions not necessarily stimulate high actual flows. It is thus important when researching or analyzing globalization to be explicit about the kind of globalization one is referring to, while acknowledging that combining both views offer a more complete perspective.

Dimensions of Globalization

Next to distinguishing between “written” de jure globalization and “actual” de facto globalization, it is insightful to disaggregate the different dimensions of globalization. One of the most obvious

transboundary connections is through international trade. Together with financial connections such as FDI, these constitute the two main categories of economic globalization.

The second dimension of globalization can be found in the political sphere. Political globalization describes the process of an emerging transnational political system that can be observed by the involvement of nations in international organizations, the adherence to international policy-making or political presence beyond the national borders, such as embassies or international NGOs.

The third dimension of globalization is social globalization. Social globalization describes the interconnectedness of people across national or regional boundaries. This interconnectedness can express itself through the ease of physical movement, both temporary and permanent, but also through the interconnectedness via social and communication media.

The fourth dimension, often incorporated in social globalization, is cultural globalization, which describes the process of increasing transmission and assimilation of values, lifestyle, culture, and consumption across boundaries.

Historically, globalization and the interconnectedness between nations was often characterized by asymmetrical North-South relations, especially in terms of trade and labour. However, South-South globalization is increasingly gaining importance, mainly due to the fast growth of China and India and an increase in regional trade agreements in the Global South (Mansoor Murshed et al. 2011).

Measuring Globalization

The KOF Index of Globalization

The KOF Index is the most often used index of globalization. A detailed review of over 100 empirical studies using the KOF index is given by Potrafke (2015), and a list of studies using the KOF index can be found at <http://globalisation.kof.ethz.ch/papers>. Starting from the premise that globalization is a broad and multifaceted concept, the KOF index incorporates a wide range of variables in its index, divided into

an economic, social, and political dimension (see Table 1). The KOF index was released in 2006 and consequently updated from 2007 on. The latest update, released in January 2018, introduced a considerable amount of innovation. The most important change is the introduction of the distinction between *de jure* and *de facto* globalization, an important distinction that is increasingly studied in the literature (see for example Quinn et al. 2011). The previous versions already used variables that represented a mix of both *de facto* and *de jure* measures, but no explicit distinction was made.

The KOF index is available yearly for the period 1970–2015. The index as well as each subindex is a score ranging from 0 to 100 with 100 indicating the maximum level of globalization, following the procedure of panel normalization. The weights for each variable are calculated using principal component analysis over a period of 10 years, while the weights on the subindices remain the same for the entire panel. Missing values are calculated using linear interpolation or substitution with the closest value. For more details and information on the definition, the dimensions and the calculation of the KOF-index, see Gygli et al. (2018).

De Facto Versus De Jure Globalization

An analysis of the *de jure* side of the index versus its *de facto* counterpart shows that it is indeed an insightful distinction to make. When looking at overall globalization for the entire sample, we see that after moving closely together for the first 20 years of the time series, from the nineties on *de jure* globalization started to increase at a higher rate than *de facto* globalization (Fig. 1, panel a). When looking at the three dimensions separately, we see diverging trends in the *de facto* and *de jure* counterparts (Fig. 1, panel b–d). A common trend in all panels of Fig. 1 is the considerable flattening of globalization in the last decade, possibly due to the lingering effect of the financial crisis. For some subindices, there is even a slight downward trend to be identified, which is typically coined as “*de-globalization*.”

To see that *de facto* and *de jure* concepts are not necessarily high correlates, one can look at the trend of financial globalization (a sub-index of economic globalization, see Table 1) over the

Globalization, Table 1 2018 KOF Globalization Index: Structure, variables and weights. (From The KOF Globalization Index – Revisited, KOF Working Paper, No. 439 by Gygli et al. 2018)

Globalization Index, <i>de facto</i>	Weights	Globalization Index, <i>de jure</i>	Weights
<i>Economic globalization, de facto</i>	33.3	<i>Economic globalization, de jure</i>	33.3
<i>Trade globalization, de facto</i>	50	<i>Trade globalization, de jure</i>	50
Trade in goods	40.9	Trade regulations	32.5
Trade in services	45.0	Trade taxes	34.5
Trade partner diversification	14.1	Tariffs	33.0
<i>Financial globalization, de facto</i>	50	<i>Financial globalization, de jure</i>	50
Foreign direct investment	27.5	Investment restrictions	21.7
Portfolio investment	13.3	Capital account openness 1	39.1
International debt	27.2	Capital account openness 2	39.2
International reserves	2.4		
International income payments	29.6		
<i>Social globalization, de facto</i>	33.3	<i>Social globalization, de jure</i>	33.3
<i>Interpersonal globalization, de facto</i>	33.3	<i>Interpersonal globalization, de jure</i>	33.3
International voice traffic	22.9	Telephone subscriptions	38.2
Transfers	27.6	Freedom to visit	31.2
International tourism	28.1	International airports	30.6
Migration	21.4		
<i>Informational globalization, de facto</i>	33.3	<i>Informational globalization, de jure</i>	33.3
Patent applications	35.1	Television	25.2
International students	31.2	Internet user	31.9
High technology exports	33.7	Press freedom	13.2
Internet bandwidth	29.7		
<i>Cultural globalization, de facto</i>	33.3	<i>Cultural globalization, de jure</i>	33.3
Trade in cultural goods	22.6	Gender parity	31.1
Trademark applications	13.3	Expenditure on education	30.9
Trade in personal services	25.6	Civil freedom	38.0
McDonald's restaurant	23.2		
IKEA stores	15.3		
<i>Political globalization, de facto</i>	33.3	<i>Political globalization, de jure</i>	33.3
Embassies	35.7	International organisations	37.0
UN peace keeping missions	27.3	International treaties	33.0
International NGOs	37.0	Number of partners in investment treaties	30.0

Notes: Weights in percent. Weights for the individual variables are time variant. Depicted are the weights for the year 2015. Overall indices for each aggregation level are calculated by the average of the respective *de facto* and *de jure* indices.

entire period for the entire sample. Figure 2 shows that the *de facto* financial globalization (measured as FDI, portfolio investment and international debt, reserves and income payments) rose at a high rate over the time period, almost doubling from a score of 34 in 1970 to 63 in 2015. The *de jure* counterpart (measuring investment restrictions and capital account openness), however, did not exhibit a clear trend, and even decreased slightly over the period from 48 to 46. This example

illustrates the importance of the choice of certain variables for measuring and analyzing globalization.

The KOF Index for Different Income Groups

Looking at globalization per income group shows that there is a clear correlation between income level and globalization: the curves retain the same relative position, with the higher income group having a higher globalization score (Fig. 3). This is in contrast with a comparison based on regional

Globalization, Fig. 1 KOF de facto, de jure and overall globalization indices, 1970–2015 – World average

Globalization, Fig. 2 KOF financial de facto and de jure globalization indices, 1970–2015 – World average

groups, for which the curves often look somewhat messier, and exhibit a less consistent ranking. This is possibly due to the influence of particular

regional events. However, richer regions are often on the higher end of the globalization spectrum.

Globalization, Fig. 3 KOF overall, de facto and de jure globalization indices, 1970–2015 – Income group averages

Globalization, Fig. 4 KOF de facto and de jure globalization indices, 1970–2015 – Income group averages

In Fig. 3, panel a, we see that overall globalisation per income group rose steadily over the observed timespan, with a slight increase in the growth rate starting from the nineties. When looking at the different dimensions of globaliza- tion per income group, we see again that the

subdivision between de jure and de facto is use- ful, as they often paint a somewhat different picture. An interesting example of this is political de facto and de jure globalization (Fig. 4). When looking at de jure political globalization, we see that the different income groups behave

fairly similar, exhibiting a strong growth over the given time period, with the exception of a drop occurring at the end of the eighties but recovering only a few years later. When looking at the *de facto* political globalization however, we see that although convergence is present, the different income groups start from a far more diverging pattern in the beginning of the time period.

Other Measures

A few other measures have been developed to measure globalization. As such there is the CSGR Globalization Index (Lockwood and Redoano 2005), the GlobalIndex (Raab et al. 2008), the Kearney/Foreign Policy index, and the Maastricht Globalization Index (Figge and Martens 2014). These indices as well as the KOF indices, take the national boundaries as its unit of measurement. This is in contrast with the Person-Based Globalization Index (PBGI) proposed by Caselli (2012). A person-based index counters overemphasis of small countries as well as underemphasis of bigger countries. However, it should be noted that weighting by population is more insightful for some dimensions than for others. Social globalization for example might be interesting to measure on a headcount basis, while for political globalization, which depends largely on national policies, this would make less sense.

Perspectives on Globalization and Its Consequences for Governance

In order to describe the consequences of globalization and ways to try to “govern” or manage it, it is useful to distinguish between at least three different perspectives on globalization, or processes that are triggered by it, described by, e.g., Woods (1998, 2000) as market-centered, state-centered, and people-centered.

The “Market-Centered” Perspective of Globalization

The “market-centered” perspective describes a process of intensification of cross-border

exchanges of technology, goods, services, finance, ideas, and ownership, led by multinational enterprises organized in global production and distribution chains, which erodes national markets, making virtually all goods and services becoming essentially “tradables” (as opposite to non-tradables, i.e., goods or services that are only produced and consumed in the local market) and leads to (the “triumph of”) global markets. Essentially, it focuses on the perspective of globalization as leading to the global expansion of capitalism. From this perspective, a quite positive prognosis on the results of globalization is derived: the demolition of *de jure* barriers, the spread of technological advances, combined with efficiency-maximizing behavior of global firms leads not only to long-term production and consumption benefits, and thus higher welfare, but also points at the new opportunities that open up for firms, workers, and consumers all over the world, and particularly also in less developed countries and regions, to gain from being inserted and/or upgraded in these global production chains (Bhagwati 2005; Wolf 2004).

At the same time, while increasing overall welfare, it is clear that this process will produce not only winners but also losers, and that benefits and the costs of globalization are often indeed incurred asymmetrically, necessitating the necessity and ability for complementary measures to be added in an effective way in order to compensate these marginalized and losing ones and try to reintegrate them in a valid and sustainable way in the global capitalist system. In essence, critics in general, and the anti-globalist movement in particular, heavily question the ability of these mitigating effects to be included and, when indeed included, to be effective, and/or, more generally, heavily criticize the ability of global capitalism to provide long-term benefits in a sustainable way (see, e.g., Della Giusta et al. 2006 for a collection of critical writings). A less extreme criticism would suggest positive effects for welfare at modest increases of globalization, that would slowly bottom out at higher levels, and may even become negative at “hyper-globalization” level, hinting that there may something as “too much globalization,” as too much of a good thing (for recent

evidence see, e.g., Lang and Mendes Tavares 2018).

A detailed overview of studies analyzing the effect of globalization focusing mainly on this more economic perspective can be found in Dreher et al. (2008) and, more recently, Potrafke (2015). The reviewed studies measure the influence of globalization on macroeconomic performance such as the size of the government, economic performance, labor markets, and capital markets, to name a few. These analyses are mostly performed on a specific geographical unit and as a consequence findings often differ accordingly. When looking at the world as a whole, the general accepted view is that globalization has a net positive effect (Dreher et al. 2008; Wolf 2004). However, the assessment of the effect of globalization on the world as a whole is ultimately a normative question, as the benefits and the costs of globalization are indeed often incurred asymmetrically. As such, studies like Wade (2004) and Dreher and Gaston (2008) conclude that globalization increases income inequality. Goldin and Reinert (2012) research in depth the complex relationship between poverty and globalization and condition the positive effect of globalization on the presence of compensatory policies or mechanisms that mitigate the effects on the actors on the losing end.

Clearly, this market-centered, somewhat “economistic” perspective is too narrow, as if once market forces are unleashed, institutions and policies will follow (Woods 1998), nation-states will see their role diminish and even evaporate and people will become global consumers, being inserted in global labor chains and sharing global values. In other words, state-centered and people-centered perspectives provide not only reactive forces but also complementary insights.

Adding State-Centered and People-Centered Perspectives of Globalization

A state-centered perspective may acknowledge that indeed, the power of nation-states may reduce in some ways as some policies may become less effective in global markets, or some state capacities, such as the ability to tax, may erode, but several counterbalancing forces occur. First of

all, as highlighted in the *de jure* globalization concept, the global integration process has been driven by explicit state policy choices, especially in Western countries. Secondly, states have been using these policies also to protect their citizens, and particularly also the losers of globalization among them, against the negative effects of globalization. Thirdly, in the absence of global markets’ ability to make good rules and regulations themselves, it requires states to come together to make and enforce these global rules and regulations. As such, rather than eroding state sovereignty, it mainly transforms it, by shifting some power to a supranational level, be it global or regional.

The need for this cooperative behavior at global level has been enhanced by globalization itself, as more of the pressing challenges of the world, such as environmental degradation, crime, and terrorism or “illegal” migration, have become globalized. As such, actions to solve them have become international public goods, necessitating interventions, such as treaties, new agencies, or regulations at regional or global level (e.g., Kaul et al. 2003). In this new globalized world order, it is important to see who exactly determines the rules in these new supranational forms of cooperation, avoiding a race to the bottom where the weakest link dominates the quality of rules. Moreover, it is also important then to monitor the extent to which less-powerful countries are amply represented or able to voice their viewpoints and concerns at the global table; in other words, what is the quality of global governance (see, e.g., Claes and Knutsen 2011).

The focus on these more nation-state centered perspectives has also shown that the evolution towards global markets did not necessarily lead to a globalized consensus on what constitutes good policies. To give one example, the “Washington consensus” has been rather successfully, leading to the gradual acceptance of more heterodox policies, also in emerging and developing countries, and increasingly being rivalled by the Peking one. And more prominently, globalization has not gone hand-in-hand with the worldwide introduction, at nation-state level, of Western-style forms of democracy.

A “people-centered” perspective adds additional insights, complexities, and counteractions, as it does not only impact people’s standards of living but also their values and the opportunities to voice them (see, e.g., Whalley 2008). Again, the proposition that (market-centered) globalization would also lead to the globalization of Western values, and a global culture, has been counteracted by strong upsurges of national and/or religious identity reassertion. It did not lead to a smoother introduction of worldwide human rights values, nor did it realize successful bottom-up promotion of democracy, from the grassroots to nation-state levels. More importantly, a people-centered perspective depicts intensified attention to the asymmetric gains of globalization and the voicing of those left behind in the process. As already stated by Singer and Wildavsky (1993), it is producing a polarized world with “zones of peace” and “zones of turmoil”; these zones of turmoil not only reflect places with a high concentration of losers of globalization in a more narrow sense but also more broadly speaking, zones than may encompass whole regions or countries that are in conflict, or post-conflict, where the state has imploded, and non-state actors have taken over basic service delivery, through all kinds of forms of hybrid governance. Clearly, this will produce increased global inequality. At the same time, increased globalization has also facilitated voicing of concerns and protest against this situation, and also facilitated attempts to escape from these zones of turmoil to the peaceful ones, leading to increased migration moves across the globe, which at the same time start to challenge the very fundamentals of the “market-centered” perspective of globalization. In its most recent form, it is also leading to an increasing wave of forms of populism also in core Western countries such as in Europe and the USA, albeit of different faces, that again threaten to challenge the core fundamentals of market-centered globalization (Rodrik 2017).

This more complex interlinkage between globalization, nation-state power, and democracy is conceptually shown by Rodrik (2011) in his so-called globalization paradox or trilemma, hinting at the fact that we cannot simultaneously

pursue democracy, nation-state self-determination, and hyper-market-centered globalization, advocating for a system of “smart globalization” in which we deliberately limit this market-centered globalization, in order to be able to have more political (nation-state) and social (democratic) support from and for those it is supposed to help.

We thank Anne van Aaken, Hein Kötz, Alan Miller, Luciano Benedetti Timm, and Reinhard Zimmermann for valuable comments on an earlier draft. All errors are ours.

Abstract

Good faith is a blanket clause under which courts develop standards of fair and honest behavior. It gives ample discretion to the judiciary and entitles a court to narrow down the interpretation of statutes or contracts and even to deviate from codified rules, from the wording in the law or the contract or to fill gaps. The law and economics literature relates bad faith to opportunistic behavior and it is accepted that in specific cases where the application of default or mandatory rules leads to opportunism or where both the law and the contract are silent on risk, the judge can resort to the good faith principle. As a result the parties may delegate part of the contractual drafting to the legal system in addition to having reduced apprehension regarding the possibility of opportunistic behavior from the other side. This allows them to keep contracts relatively short and reduces the costs of defensive strategies.

Definition

Good faith is a blanket clause in civil law under which courts develop standards of fair and honest behavior in the law of obligations, especially in contract law and – to some extent – in the law of property. Courts also define legal consequences resulting from the violations of such standards, such as reliance damages, expectation damages, injunction, imposing a duty of conduct, and invalidation or validation of a contract. The good faith principle entitles a court to narrow down the interpretation of statutes or contracts and even to deviate from codified rules, from the wording in the law or the contract or to fill gaps. Courts use it as a last resort, if and only if the contract itself or the rules of contract law lead to grossly unfair results. “Good faith” also has found its way into jurisdictions other than those of civil law, as well as into the public international law of contracts and international law in general.

Introduction

The roots of the good faith principle can be traced back to Roman times. Even today Cicero’s writing

on good faith (De Officiis 3.17 (44 BC)) from more than 2,000 years ago reads as fresh as if it had just been published. It comes close to the modern description of “opportunistic behavior” that economists have developed in recent decades: “These words, good faith, have a very broad meaning. They express all the honest sentiments of a good conscience, without requiring a scrupulousness which would turn selflessness into sacrifice; the law banishes from contracts ruses and clever maneuvers, dishonest dealings, fraudulent calculations, dissimulations and perfidious simulations, and malice, which under the guise of prudence and skill, takes advantage of credulity, simplicity and ignorance” (quoted from Association Henri Capitant and Société de législation comparée 2008). The contemporary content of the principle is not well defined. Its scope is also subject to debate, with some scholars regarding it as a rule of contract law or of the law of obligations and with others relating it to the whole body of civil law.

Objective good faith is an objective standard of behavior, especially for contracting parties. Contract law, with its mandatory and default rules, tries to allocate risk and imposes contractual, pre-contractual, and post-contractual duties and risks fairly and honestly in the way self-interested parties would have chosen had they considered the problem *ex ante* at the time of contract formation. However, due to the features of a specific case, the application of these legal rules can possess unintended and absurd consequences in individual cases. And even though the black letter rule mostly leads to the desired consequences, it might lead to the opposite in some. In such cases, the good faith principle allows courts to deviate from the black letter rules of contract law or from the contract itself. If the courts find the application and the result of a legal norm in a specific case to be absurd, because they still allow opportunistic exploitation or grossly inefficient risk allocation, they can deviate by using the good faith principle. And they can give the law flexibility if unforeseen contingencies transform fairness into dishonesty and efficient into grossly wasteful allocation of risk. This not only provides adaptability to new circumstances but also saves the parties’ transactions costs.

More specifically, by knowing that a court has the option to intervene, parties are less inclined to write every contingency into the contract, thus making contracting less costly and defensive measures of parties less necessary.

The principle is not without pitfalls and therefore subject to criticism. Firstly, it gives ample discretion to the judiciary, which can be and has been misused for importing ideology, including totalitarian ideology, into contract law or for promoting private opinions of judges about what they regard as just. Secondly, it might foster judicial activism if the judiciary develops the law proactively in such a way that it replaces parliament. Thirdly, the principle might be inappropriately used to redistribute wealth from the rich to the poor party by adopting a deep pocket approach. Finally, following Hayek, judges who intervene in a contract might not as outside observers have the information for reliably acting in the *ex ante* interest of honest parties, even if they have the best intention in doing so.

The Good Faith Principle in the Legal Doctrine

The good faith principle is widely used in all civil law countries, for instance, in Germany, Switzerland, Turkey, France, Italy, and the Netherlands. It is also recognized in the US Uniform Commercial Code as well as in unification instruments of private law, including the UN Sales Law, the UNIDROIT Principles for Commercial Contracts, and the Principles of European Contract Law. Good faith is relatively new in American law, but seemingly it also caught on quickly. On the other hand, English law does not recognize a general duty of good faith. In fact, English lawyers think that the courts should only interpret contracts and refrain from allocating risks by way of the good faith principle (Musy 2000; Goode 1992). This does not imply that English contract law cannot correct for absurd consequences of routine decisions, yet the English principles, such as “fair dealing,” are narrower than the good faith principle and do not transfer the same amount of discretionary power to the judiciary. Scholars of comparative law have expressed the view that if one looks at how hard

cases of contract law are actually decided in common law and civil law jurisdictions, the differences might be less pronounced than it seems on the surface (Zimmermann and Whittaker 2000). Judge Bingham expressed a similar view with the following words in *Interfoto Picture Library Ltd. v. Stiletto Ltd.* (1988) 2 W.L.R. 615 (p. 621): (England has no) “overriding principle that in making and carrying out contracts parties should act in good faith ” but added that on the other hand “English law has, characteristically, committed itself to no such principle but has developed piecemeal solutions in response to demonstrated problems of unfairness.”

A major point of critique of the principle of good faith is its generality and broad scope. This is also in close relationship with the critique that the judiciary can arbitrarily interfere with the contract by using this principle. However, it could be argued that the risk of intolerable legal insecurity and unpredictability is eliminated. In those jurisdictions where the principle is accorded an important role, it is split up into categories and subcategories (Hausheer and Jaun 2003; Grüneberg 2010). Through this subcategorization, an out-of-hand use of the principle by the courts in these jurisdictions is seldom, with each subcategory applying the facts of the case to a series of judge-made tests that possess particular legal consequences on passing the test.

In jurisdictions that recognize a general principle of good faith, there exists a variety of established legal dogmatic forms that define terms and conditions under which the principle of good faith is to be used. Moreover, they also define particular legal consequences if a defendant has violated a standard of behavior. These legal dogmatic forms, all of which are derived from the general good faith principle, provide it with an internal structure, which checks it against willful use. These subcategories are mainly as follows: culpa in contrahendo; contract with protective effects for a third party; liability for breach of trust; adaptation of the contract to changed circumstances (*clausula rebus sic stantibus*); side obligations from a contract (breach of which constitutes a case of breach of contract); obligation to contract; principle of trust in formation,

interpretation, and gap filling of legal transactions; misuse (abuse) of rights; and forfeiture.

The well-established subcategories of good faith substantially eliminate the risk of a judge’s arbitrary interference. As a matter of fact, there is a general scholarly agreement on the conditions for resorting to any of the subcategories as well as on the legal results that follow. Still, despite such concrete dogmatic forms, in the jurisdictions where the good faith principle is recognized, it is accepted that such general principles should be used as a last resort, if and only if the formal rules of the contract law lead to absurd consequences. If the good faith principle is a monster, as scholars (Zimmermann and Whittaker 2000) once claimed, it has been domesticated as a farm animal. From an economic perspective, this means two things. First, the good faith principle is a delegation norm for the judiciary. It entitles judges to manually control the law if it does not fulfill its functions. It serves parties if the judges are knowledgeable, loyal, and not corrupt but does a disfavor to them otherwise. Secondly, the development of a tight internal structure is a commitment by the judiciary to credibly signal to the legal community that it applies the principle with self-restraint and self-discipline, ruling out willful, ideological, or biased decisions.

The Good Faith Principle as a Norm to Curb Opportunism

The law and economics literature mainly relates the good faith principle to the prevention of opportunism. According to Summers (1968), good faith is an excluder which “has no general meaning or meanings of its own, but which serves to exclude many heterogeneous forms of bad faith.” Burton (1980) relates bad faith to the exercise of discretion by one of the contractual parties concerning aspects of the contract, such as quantity, price, or time. Accordingly, “Bad faith performance occurs precisely when discretion is used to recapture opportunities forgone upon contracting – when the discretion-exercising party refuses to pay the expected cost of performance.” Similarly, while defining good faith,

Miller and Perry (2013) refer to the enforcement of the parties' actual agreement. More specifically, the authors argue that the good faith principle protects the reasonable expectations of the parties, which they had while contracting. They criticize however that in the USA in contrast to definitions, courts often resort to community standards, based on what people actually do, and that this can undermine the function of contract. They argue that the good faith principle in US contract law should be based on normative ideas like welfare maximization or the golden rule and not on purely empirical observations. Mackaay (2009) defines bad faith as the legal term for opportunism. Richard Posner describes the principle in a similar way: "The concept of the duty of good faith like the concept of fiduciary duty is a stab at approximating the terms the parties would have negotiated had they foreseen the circumstances that have given rise to their dispute. The parties want to minimize the costs of performance. To the extent that a doctrine of good faith designed to do this by reducing defensive expenditures is a reasonable measure to this end, interpolating it into the contract advances the parties' joint goal" (Justice Posner's opinion from the decision *Market Street Associates Limited Partnership v. Frey*, 941 F.2d 588, 595).

Elements of Opportunistic Behavior

Williamson (1975) famously defines "opportunism" as "self-interest seeking with guile." In fact, strategic manipulation of information and misrepresentations are to be deemed as opportunistic. The same applies to hidden action aimed at reducing the quality of performance.

According to Dixit, opportunistic behavior is the "whole class of actions that tempt individuals but hurt the group as a whole" (Dixit 2004). Opportunistic behavior is inefficient because it increases transaction costs and reduces the net gain from the contract (Sepe 2010; Mackaay 2011). The risk of opportunism encourages parties to take defensive precautions and write longer contracts to prevent opportunistic behavior as well as the harms that might arise from it. Opportunistic behavior could even incentivize parties to take strict precautions, such as foregoing

a contemplated contract altogether. If many contractors were to choose this option, this could destroy entire markets (Mackaay 2011).

Muris (1981) defines opportunism as behavior which is contrary to the other party's understanding of their contract – even if not necessarily against the implied terms of the contract – and which leads to a wealth transfer from the other party to the performer. Cohen (1992) defines it as "any contractual conduct by one party contrary to the other party's reasonable expectations based on the parties' agreement, contractual norms, or conventional morality." Similarly, Posner (2007) defines opportunism as taking advantage of the other party's vulnerability.

Mackaay and Leblanc (2003), who regard good faith as the opposite of opportunism, propose a test to operationalize opportunistic behavior: "an asymmetry between the parties; which one of them seeks to exploit to the detriment of the other in order to draw an undue advantage from it; the exploitation being sufficiently serious that, in the absence of a sanction, the victim and others like him or her are likely substantially to increase measures of self-protection before entering into a contract in the future, thereby reducing the overall level of contracting."

The Necessity to Curb Opportunistic Behavior with a Blanket Clause

The role of contract law can be explained as an endeavor to guarantee the fairness of the contract in the sense of avoiding opportunistic behavior (Posner 2007; Kaplow and Shavell 2002) and through the cost-efficient allocation of risk (Harrison 1995; Schwartz 2003; Schäfer and Ott 2004). In accordance with the purpose of contract law, if the good faith principle were used exclusively to curb opportunistic behavior and to allocate risks in a cost-efficient way in cases in which the established rules of contract law permitted opportunism, it would be regarded as a valuable corrective mechanism giving flexibility and innovativeness to contract law without questioning its rationale for facilitating win-win constellations under fair conditions.

A court can enhance efficiency through the good faith principle in three ways: by (i) not applying a mandatory rule (for instance, by

declaring a non-notarized real estate sales contract as valid), (ii) refraining from the application of a default rule (for instance, by declaring the rule under which partial delivery can be rejected as invalid), and (iii) allocating risks when the law or the contract is silent (for instance, by imposing a non-competition clause) (Schäfer and Aksoy 2015). In the first two cases, the law specifies the risk, but it is clear that the specification of the risk in such a particular case is questionable and gives rise to opportunism. In other words: in such a specific case, applying the norm delivers absurd results, with the blanket clause of the good faith principle on the other hand providing the judge with flexibility that he would otherwise not have had. Finally, both contract and default rules may be silent on a matter consequentially leading to a result that may be neither fair nor cost-saving. In such cases, the principle of good faith can provide efficient risk allocation.

Finally, in line with the legal reasoning, Mackaay (2011) argues that good faith is a last resort tool for preventing opportunism. The author states that there are various anti-opportunism concepts in the law, but when none of these concepts manage to prevent opportunism, the judge will use the good faith principle. Economically speaking, the blanket clause of good faith is a delegation of decision-making authority to the judiciary. If contract law fails to fulfill its aim of curbing opportunistic behavior and allocating risk in a cost-efficient way, thus to guaranteeing fairness and honesty, the judiciary is given the competency for guaranteeing the rationale of contract law, even if this implies deviation from legal rules or from the contract itself. It is obvious that such a delegation norm can work only in jurisdictions in which judges are loyal to the spirit of the law, as well as knowledgeable and non-corrupt.

Good Faith and the “Social Function of Contract”

The self-restriction employed by courts when using the good faith principle has contributed significantly to its international recognition, expansion, and widespread use in many countries and codes and has helped to silence criticism. It is used to maintain the fairness of the contract. It is

employed as a last resort; it has developed a rich internal structure, thus preventing willful use. Under these conditions, the good faith principle saves transactions costs, and the business community as well as the whole legal community can regard it as a valuable service.

This proposition comes, however, with a caveat. In some civil law countries, including those of continental Europe, it has been argued that courts have sometimes used the good faith principle to achieve a proper distribution of wealth by interpreting the law or filling gaps in contracts in favor of parties such as consumers, employees, and tenants. Sometimes, such decisions can be interpreted as a correction of market failures, but sometimes they are indicative of a deep pocket approach, meaning redistribution of wealth to the poorer party, even if this neither corrects unfairness nor market failure and is contrary to the terms of the contract itself and to black letter law. This is motivated by distributive justice but comes at the cost of protecting only the insiders not the outsiders and increasing rather than decreasing the costs of using the market making it difficult or even impossible for people without reputation to make promises.

In some countries, the principle is openly used to promote the redistributive goals of social justice, which are usually achieved through the welfare state and statutory laws. In Brazil a case law is emerging in which the good faith principle is not merely used to maintain fairness in the sense of honesty. Under the legal principle of the “social function of contract” the good faith principle sometimes helps to achieve social justice by redistributing income *ex post*. This can destroy the mutual benefit from a fair contract in which all partners abstain from opportunistic behavior. It seems that such features of “good faith” can be found more often in countries without an effective welfare system or public and private insurance systems. If contracting parties must, however, expect that under certain conditions, in spite of their fairness and honesty, they are stripped from the benefits of the contract *ex post* by the use of the good faith principle, they might abstain from such contracts altogether. This can lead to dysfunctional markets and considerable costs for

society. The unintended consequences of such interventions, for instance, price ceilings, have been widely discussed in the literature.

Timm (2008) has reviewed some of the Brazilian case law, which spans from not allowing interest on interest, imposing interest rates *ex post* which are lower than those for government bonds or an injunction requiring an insurance company to cover a surgery or treatment not provided according to the policy, or even preventing an unpaid utility from cutting the supply of electricity. In a lawsuit initiated in Rio de Janeiro, a tenant failed to pay rent for consecutive months. Hence, the landlord sued the tenant bringing a claim for eviction from the property, which the tenant ran as an asylum for the elderly. Despite the Brazilian Landlord-Tenant Law (Law No. 12112/2009) which set forth that a failure to pay rent for consecutive months is a valid reason for eviction, the Appeal Court of Rio de Janeiro ruled for the prolongation of the deadline for an indefinite period of time in order to protect the elderly residents, thus making the landlord a charitable donator. Such decisions help the individual claimant, but not the poor as a group as they deny them the possibility to make credible promises and commitments making market transactions more difficult for them.

According to Nóbrega, the new 1988 Constitution brought about judicial activism by way of establishing a principle- and standard-oriented “social welfare legal order in which the judge had the mission of maintaining social justice (Nóbrega 2012). Consequently, the Brazilian Civil Code regulated both the good faith principle and the social function of contract. Within this scope, the social function of contract, which is derived from the principle of good faith, is regulated by Article 421 of the Brazilian Civil Code as follows: “the freedom to contract shall be exercised by virtue, and within the limits, of the social function of contracts.” Although the law refrains from defining the “social function of contract,” a prevailing definition of this broad concept is made by Diniz (2007) as a kind of contractual “super-principle,” comprising precepts of public order, good customs, objective good faith, contractual equilibrium, solidarity, distributive

justice, etc. More specifically, the author argues that the social function of the contract should comprise every constitutionally and/or legally recognized value that might be said to have a “collective” or “nonindividualistic” character.

Conclusion

The law and economics literature relates bad faith to opportunistic behavior, which increases transaction costs, reduces the net gain from the contract, and allows one party to achieve unfair re-distributional gains. Contract law is mainly the endeavor to curb opportunistic behavior and to maintain the cost-efficient allocation of risk. In specific cases where the application of default or mandatory rules leads to opportunism or where both the law and the contract are silent on risk, the judge can resort to the good faith principle. Its use allows for the correction of opportunistic behavior for all those cases in which the black letter law fails to do so. It provides ample discretion to the judiciary and has – from a historical perspective – been misused and heavily criticized. This has not, however, prevented it from becoming an important legal norm in a rising number of jurisdictions and codes.

The good faith principle lost its fearsome features mainly for three reasons. First, its contemporary use is constrained to preserve fairness and honesty among parties, but does not burden honest parties with obligations from community values or social justice in the sense of redistributing income *ex post* for social purposes. Some exceptions exist however: sometimes camouflaged, sometimes – like in Brazil – easily visible, and more explicit. Secondly, courts use the good faith principle as a last resort when all other routines of judicial decision-making are exhausted yet still lead to absurd legal consequences that allow for opportunistic exploitation or grossly inefficient risk allocation. Finally, the good faith principle has a deep interior structure with subcategories providing routines, tests, and legal consequences resulting from these tests. This makes it difficult for judges to misuse the principle for promoting private or ideological

views about justice and becoming disloyal to the law. Decisions of an individual judge using the good faith principle without observing these self imposed dogmatic constraints are likely to be uplifted by a higher court. These features have led to the increasing confidence that the good faith principle provides a valuable service to parties and enables them to delegate part of the contractual drafting to the legal system. Moreover, it has reduced their apprehension regarding the possibility of opportunistic behavior from the other side. This allows them to keep contracts relatively short and reduces the costs of defensive strategies. In comparison, in jurisdictions which either reject the principle (England) or in which the principle has no long-lasting tradition (USA), there is less delegation and contracts are extensive, are more expensive to draft, and contain long laundry lists of required or impermissible behavior from parties. In the literature, other reasons have been discussed as to why English and US private contract law implies less delegation to the judiciary. This is only one of them.

Good Faith and Game Theory

Caspar Rose
Copenhagen Business School, Copenhagen,
Denmark

Abstract

This article shows how game theory can be applied to model good faith mathematically using an example of a classic legal dispute related to *rei vindicatio*. The issue is whether an owner has a legal right to his good if a person has bought it in good faith by using updated probabilities. The article illustrates that a rule of where good faith is irrelevant Pareto dominates a rule where good faith may protect an innocent buyer.

Synonyms

Using updated beliefs in modeling good faith and its impact on Pareto efficiency

Definition

If a potential buyer incurs effort and the new updated beliefs result in an increased probability that the good is stolen compared to the initial beliefs, then a buyer is said to be in *bad faith*; if, however, the probability decreases, he is said to be in *good faith*. The buyer is also in bad faith, if he deliberately chooses to stay in ignorance.

The Advantage of Using Game Theory

One may ask, what are the benefits from using game theory for modeling good faith? Game theory relies on a number of assumptions, in particular, the full rationality by the players, which means that the players' objective is to maximize their expected utility; see, e.g., Rasmussen (2004). This means that players make rational choices and have stable preferences.

Game theory has the advantage that it takes into account the players strategic interdependency meaning that the players utility does not only depend on their own actions but also on the opponents actions and vice versa or mathematically expressed: $U_i(a_i, a_j)$ and $U_j(a_j, a_i)$.

Game theory is well suited for analyzing different legal settings, in particular, the incentive effects of different legal rules. Players know what kind of actions is available for them, which naturally is influenced by the legal status, e.g., the possible choice of remedies of breach in a contractual relationship. The players know what the expected outcomes from a sequence of actions are. This is presupposed to be common knowledge among the players. This does not mean that players have perfect information. However, by applying the proper equilibrium concept, one may be able to predict the player's actions, i.e., the outcome of the game. The basic solution concept is the Nash equilibrium where each player plays a best response to each other's actions. This must be refined depending on whether the game is static/dynamic with perfect or imperfect information. In the following analysis, the applied solution concept is the so-called subgame perfect Nash equilibrium which is used for dynamic games with perfect information, but it can include external uncertainty (moves by Nature). In short, game theory is a powerful tool to study games with strategic interdependency where the legal setup defines the player's action spaces; see, e.g., Landes and Posner (1996) for a study of legal rules and strategic interdependency as well as Baird et al. (1998) for an excellent example of how legal rules can be studied using game theory.

The Usefulness of Using Game Theory in Law and Economics

Good faith has been analyzed using game theory, but it turns out that game theory is very well suited for analyzing the economic effects of legal rules. The basic setup of using game theory in law and economics is to study different games under different legal regimes with the same players. To illustrate, it is well known that car drivers and pedestrians behave differently under a regime of strict liability or negligence. Specifically, a car driver may show less precaution under a negligence rule, whereas the pedestrians may be quite careful walking on the sidewalk. In short, law and economics that rely on game theory may be formulated in the following single equation.

$$\Delta \text{Rules/court rulings} \Rightarrow \Delta \text{actions} \\ \Rightarrow \Delta \text{payoffs} \Rightarrow \Delta \text{incentives} \Rightarrow \Delta \text{efficiency}$$

The equation simply displays causal impact of changing the rules or court rulings on efficiency, where Kaldor-Hicks efficiency may be preferred for practical reasons in most cases. Most game theories assume that players are risk neutral, but this assumption may not hold in all cases. Introducing risk aversion in the good faith analysis may extend the analysis to include optimal risk allocation between the parties, including the relevance of insurance, which may serve as an interesting future research topic.

An Illustration: The Sale of Stolen Goods

A person who is offered a television in the parking lot outside a bar is rarely in doubt that the television is stolen. In other situations, a person may find it difficult to determine the likelihood that the offered good is stolen. This is the case when used goods are offered for sale outside private homes (garage sales) or sold through pawnshops. In fact, most stolen goods are traded in workplaces where many people interact and rarely in sinister places. A consumer buying

goods in a shop may well presume that the shop seller has legal title to sell the good. However, in many other cases, this is not the case, e.g., especially in auctions on the Internet. There have been numerous cases where a buyer in “good faith” had been contacted by the original owner of a good or artifact, claiming the item handed over. This is a classical legal dispute that goes back to ancient times.

The term *rei vindicatio* stems from Roman law and describes an owner’s right to claim his good back from a person who unlawfully has the good in his possession. *Natural law* or *jus naturale* was the dominant legal foundation for the majority of European countries that coincide with Roman law. The rule was an absolute doctrine of vindication, which was regarded as an inherent attribute embedded in the notion of property rights at that time.

Different legal systems in modern times prescribe various solutions to this fundamental problem of property rights; see Levmore (1987) as well as Mattei (1996) for civil law countries. Some legal systems place the entire risk on the buyer, whereas other systems place the risk on the initial owner. In the latter case, this is the case if the buyer is in so-called good faith. Obviously, the choice of legal rules influence the parties incentives, especially how many resources the initial owner is willing to incur to protecting his property and assets as well as a potential buyers costs of verifying the ownership of the offered good; see Cooter and Ulen (2000).

However, there is a strong strategic interdependency in this situation. A potential buyer, who knows that an initial owner has spent much effort to protecting his assets, implies that the likelihood that the offered good is stolen is small, whereas the contrary is the case in the opposition situation. The key issue is what kind of legal system is most efficient from an economic perspective. The analysis of this question can be analyzed using game theory that includes strategic interdependency between a potential buyer and an initial owner of a good. In fact it turns out that the choice of legal rules in this situation influences parties differently, which has consequences for efficiency.

Modeling Good Faith in the Stolen Good Case

The following results rely in Rose (2010) where the full model is outlined. The article also contains a comprehensive description of how the issue of good faith is treated in several different jurisdictions, including what constitutes good faith. The following is a brief outline of the dynamic game theoretical model with perfect information. There are two players, an initial owner and a potential buyer, who must decide how much effort to spend on protecting his good (denoted c), whereas the potential buyer must determine how much to spend on verifying the ownership (denoted e). Even though there is “perfect information,” so the solution concept is subgame perfect Nash equilibrium; there is still randomness which is modeled by introducing Nature as a probability device, denoted $\pi(c)$ which is decreasing in c .

Let $\Pi(c,e)$ denote the potential buyer’s “posterior” probability or “updated beliefs” that the good is stolen, given e , which is specified as follows:

$$\begin{aligned}\Pi(c,e) &= \lambda\pi(c) \text{ if } e = e_H \text{ where } \lambda \in [0, 1/\pi] \text{ and} \\ &= \pi(c) \text{ if } e = 0\end{aligned}$$

These probabilities reflect the idea that a buyer after incurring effort e may revise his initial beliefs that the good is stolen, so that the posterior beliefs that the good is stolen may either increase or decrease. If the buyer incurs effort e and the new updated beliefs result in an increased probability that the good is stolen compared to the initial beliefs, then a buyer is said to be in *bad faith*, i.e., $\lambda\pi(c) > \pi(c)$; if, however, the probability decreases, i.e., $\pi(c) > \lambda\pi(c)$, then he is said to be in *good faith*. The buyer is also in bad faith, if he deliberately chooses to stay in ignorance, i.e., when $e = 0$.

The basic idea is that if it is common knowledge that there is a 20% probability that the good is stolen, but that the posterior beliefs after trying to verify the ownership shows that the good may be equally stolen, then he is said to be in bad faith. The potential buyer is said to be in good faith if the

posterior beliefs have shown a reduced likelihood that the good may be stolen.

Furthermore, it is assumed that if a buyer accepts an offer to buy a good that might be stolen this will stimulate criminal activity, since it becomes easier to sell stolen goods; hence, the market for stolen goods becomes more profitable. This will cause more people to enter the market, and as a consequence, the probability of theft increases in the economy; see, e.g., Benson and Mast (2001) for a study on private security services as well as Ayres and Levitt (1996) who show that such crime reduction may generate externalities.

The probability of theft also depends on a potential buyer’s decision, i.e., $d = \{\text{accept}, \text{reject}\}$ with the following specification:

$$\begin{aligned}\pi(c,d) &= \varphi\pi(c,d) \text{ if an offer is accepted,} \\ &\quad \text{where } \varphi \in [1, 1/\pi] \text{ and} \\ &= \pi(c) \quad \text{if an offer is rejected}\end{aligned}$$

With a rule where good faith is legally irrelevant, the good is given back to the initial owner irrespective of any good faith, and the purchaser’s utility declines to 0, but at the same time, the initial owner’s utility V is restored. It is assumed that the initial owner can always document that she is the rightful owner. In contrast, the good is only handed over to the initial owner under a *good faith rule* if the buyer was in bad faith and if the case is solved by the police. It is assumed that goods cannot be consumed as well as the original owner’s utility declines by the value of the good taken away.

We first start up by analyzing what is the optimal situation which afterward is compared with the two regimes, i.e., with good faith and one without good faith.

It can be shown that a regime that does not take into consideration the good faith of a buyer of a stolen good will induce a buyer to accept any offer. The buyer will avoid spending resources on examining the ownership of the offered good. On the other hand, it can be shown that under a rule of law where good faith plays a decisive role in determining property rights, there is a positive probability that a potential buyer will incur costs

in order to verify ownership. Compared to a rule of law where good faith is irrelevant, an owner will spend more resources on seeking to protect his property from being stolen. However, more importantly, a rule where good faith is irrelevant, Pareto dominates a rule where good faith may protect an innocent buyer, as a potential buyer wastes resources on trying to verify ownership and owners of goods incur higher costs in order to deter burglars from stealing their property. This is the case only under the assumptions especially that parties are assumed to be risk neutral. Most game theoretic models assume risk neutrality; hence, payoff functions are simple to work with as they are not concave, as is the case when players are risk averse.

Good Faith in Other Settings

The abovementioned example focuses on a central aspect where good faith may be vital. However, there are other examples such as within tort law. To illustrate, the business judgment rule protects top management from liability, but the legal doctrine has severe incentive effects that can also be analyzed with game theory. According to this doctrine, CEOs and board members are not liable for a decision that results in huge financial losses, as long as it makes the decision on a well-informed basis. Inferior business skills do not constitute a basis for holding an incompetent management liable. A decision which is based on a business judgment made in good faith, but which results in a substantial financial loss for the company, does not make the management liable to legal proceedings by shareholders or creditors.

One may argue that the business judgment rules increase shareholder returns over a situation where management conduct is subject to a strict negligence standard. The rule allows management to engage in more risky projects without the fear of being held personally liable. It is by no means certain that the courts have sufficient knowledge to determine *ex post facto*, whether a business decision should have been taken or not. In the absence of the business judgment rule, the volume of litigation would increase and transaction costs would rise, not only due to higher fees for lawyers

and court fees but also because of increased managerial opportunity costs. The basic idea is that there is a strategic interdependency between managers and shareholders. Good faith protects managers from legal liability, but it also influences the return of the shareholders and their incentives to sue management, which is analyzed in Rose (2011).

Gordon Tullock: A Maverick Scholar of Law and Economics

Richard E. Wagner

Department of Economics, George Mason University, Fairfax, VA, USA

Abstract

This essay sketches the central features of Gordon Tullock's (1922–2014) contributions to law and economics. My reference to Tullock as a

“maverick scholar” is to indicate that he stood apart from the mainstream of law and economics scholarship as this is represented by Richard Posner’s canonical statement that the common law reflects a relentless pursuit of economic efficiency. In contrast, Tullock denied efficiency claims on behalf of common law. Examination of Tullock’s contrary claim illustrates how any analytical claim necessarily rests on and is derived from some preceding set of conceptual presuppositions because such qualities as “efficiency” are not objects of direct apprehension but rather are inferences derived from particular theoretical frameworks.

Biography

It is worthwhile noting that Tullock’s only academic degree was a JD from the University of Chicago in 1947. He was also an undergraduate at Chicago, enrolling in 1940, and was eligible to receive his baccalaureate degree but elected not to pay the \$5 fee required to obtain it because he was already eligible to enter law school and recognized that the law degree he would soon receive would trump a bachelor’s degree. His legal studies were cut short, however, by his being drafted into the Army in 1943, where he served in the Infantry and entered into France a week after the D-Day landing in June 1944. After the war, Tullock returned to Chicago to finish his legal program. Tullock spent a few months as a practicing attorney upon graduation from Chicago and then spent 9 years with the US Department of State, including assignments in China, Hong Kong, and Korea. While with the Department of State, Tullock published three papers in major economics journals, all on Asian topics. He had also written a manuscript that was finally published in 1965 as *The Politics of Bureaucracy*, in which he sought to systematize some of his experiences and observations while working with the Department of State. While Tullock recognized that neither legal nor diplomatic practice was how he wanted to live his life, he nonetheless carried into his subsequent academic scholarship the practice-

oriented orientation toward his material that his legal and diplomatic activities entailed.

Gordon Brady and Robert Tollison (1991) describe Tullock as a “creative maverick” with respect to public choice theory, and in this designation, they are surely right. Tullock was equally the creative maverick with respect to law and economics. It should be noted that his work in what would generally be considered law and economics is a relatively small portion of his full body of work. This smallness can be seen directly by examining the ten volumes of Tullock’s *Selected Works* that Charles Rowley (2004–2006) collected. *Law and economics* was the title of one of those ten volumes. In addition, about 10 % of the first volume titled *Virginia Political Economy* is classified as pertaining to law and economics. The preponderance of Tullock’s *Selected Works* was distributed across such fields of inquiry as public choice, rent seeking, wealth redistribution, bureaucracy, social cost, social conflict, and bioeconomics.

Yet we may doubt that any exercise in counting pages can give an accurate representation of Tullock’s mind at work. An observer might distribute Tullock’s works across discrete fields to provide a scheme of classification, but for Tullock his scholarly activities reflected a mental unity across these superficially diverse fields of inquiry. There was an animating form to Tullock’s scholarly inquiries and with that form brought to bear on diverse particular objects of inquiry. With respect to Isaiah Berlin’s (1970) essay on Tolstoy, Tullock was surely more the hedgehog than the fox. In his survey of Tullock’s scholarship as of the mid-1980s, Richard Wagner (1987: 34) asserts that “someone writing a survey of Tullock’s works would surely think he was surveying the work of the faculty of a small university.” With respect to his substantive interests, Tullock’s scholarship made significant contact with such university programs as public administration, philosophy, history, biology, sociology, criminology, military science, international relations, and Asiatic studies, in addition to his contributions to law, economics, and political science. Despite this substantive variety within Tullock’s body of work, his varied inquiries sprang from and reflected a

common analytical core, which I shall explore briefly with particular regard to his scholarship in law and economics.

A. How do law and economics fit together? Melvin Reder (1999) reminds us that economics is an intensely contested discipline. So, too, is law. So how is the compound term “law and economics” to be construed when scholars have a menu of options available to them for thinking about economics and also about law? There are several ways that an economist can theorize about his or her object of interest. A legal scholar faces the same situation.

The primary concept of economic theory is the abstract noun designated as a “market economy.” Economists use this idea in explaining how it is that economic activities within a society are generally coherent and coordinated even though there is no person or office who creates that coherence. To be sure, a good number of economists find fault with market outcomes and seek to explain how political power can be deployed to secure what that economist regards as improvement. Nonetheless, the fundamental mystery of economic theory is to explain how societies exhibit coherence and coordination even though each member of that society operates mostly in self-directed fashion. The central answer economists give to explain this mystery relies upon the presence of an institutional framework grounded in the principles of private property, liberty of contract, and freedom of association. This institutional framework brings the legal order directly into the analytical picture, for the efficacy of the market order depends on the quality of the complementary legal framework. Hence, law and economics are two sides of the proverbial coin.

There are, however, different frameworks for economic analysis, and those different frameworks will in turn commend different orientations toward the relationship between law and economics. What Melvin Reder (1982) describes as Chicago economics rests on the twin claims that people maximize given utility functions and that market clear. These claims generate the Pareto efficiency of competitive equilibrium. An economist who thinks that the Pareto efficient character

of competitive equilibrium provides a good analytical window for examining economic activity will require a complementary legal framework should that economist choose to explore legal doctrines and procedures. Richard Posner’s (1973) animating claim is that the array of common law doctrines and procedures can be rendered coherent by the principle that they reflect the promotion of economic efficiency within society. Posner’s claim about law is thus complementary with Reder’s claim about the efficiency of competitive equilibrium, when coupled with the further claim that the competitive model is a good analytical window for viewing economic activity within society.

Equilibrium theory is not the only window through which economic phenomena can be viewed. One problem that arises with this approach to economic inquiry is that change comes as exogenous shocks to equilibrium and not as internally generated features of a dynamic economic process. Someone who thinks in terms of the continual generation of change as a quality of an economic system will likewise and necessarily recognize that conflict and also limited and distributed knowledge is part of that system. This alternative analytical window renders claims on behalf of efficiency dubious, mostly because the dynamic economic process is simultaneously extinguishing and creating profit opportunities, with new commercial plans continually being formed simultaneously with other commercial plans being abandoned. Social processes are naturally turbulent and there is no God’s-eye vantage point from which efficiency can be determined. This view of social economic processes, which was Tullock’s view, will lead in turn to the examination of legal doctrines and procedures through a different analytical window than through which an efficiency-always theorist would use.

James Buchanan (1987) argues that Tullock was a “natural economist.” By this, Buchanan meant that Tullock thought naturally in terms of the universal quality of the logic of choice and economizing action, rendering Tullock a theorist in the style of *homo economicus*. There is no small irony in this description, given that one of Buchanan’s widely recognized claims is that

economics should be about exchange and not choice. For Tullock, however, the logic of choice was only a point of analytical departure. It was never a destination, for Tullock was always a social theorist who never reduced society to a representative agent. Tullock was a theorist of interaction, perhaps more so than Buchanan, and not a theorist of choice, as Wagner (2008) explains in his comparison of Tullock's *Social Dilemma* and Buchanan's *Limits of Liberty*.

For Tullock it is necessary to distinguish the form by which a theory of utility maximization is expressed from the substantive content of particular instances of human action, all of which are capable of being rendered intelligible within that formal shell. The postulate of rational action means simply that people seek to succeed and not fail in their chosen actions. This is a meta-physical ordering principle and not some behavioral hypothesis. Albert Schweitzer and Adolf Hitler were both utility-maximizing creatures who pursued disparate plans of action that other people appraise to strikingly different effect, but with that difference reflecting the importation of substance into form. George Stigler and Gary Becker (1977) argued that the core of economic theory should rest on the presumption that preferences are invariant across time and place. In contrast, Tullock's analytical core was more like what Ross Emmett (2006) expressed in speculating on what Frank Knight would have said in response to Stigler and Becker. It's also similar to the contrast Richard Wagner (2010: 11–16) advances between neo-Mengerian and neo-Walrasian research programs.

The form of Tullock's theorizing was grounded in rational choice, but for Tullock form was only partly biologically or genetically determined. Tullock would not reduce economics to ethology because continuing and creative social interaction also resided within his analytical core. This brought continuing conflict and continual novelty into his social theory. In other words, Tullock's theoretical framework was one of spontaneous ordering and creative evolutions, as Todd Zywicki (2008) recognizes in his examination of Tullock's critique of the efficiency claims often made on behalf of common law.

I don't recall ever seeing or hearing Tullock refers to Carl Schmitt's (1932) treatment of the autonomy of the political in society, which expressed the idea that politics could never be reduced to law through constitutional design. Yet in a 1965 essay on *Constitutional Mythology* which is not included in his *Selected Works*, Tullock embraced the impossibility of eliminating politics through constitutional law. For Tullock, law and politics were inseparable, and both domains were populated by economizing creatures that gave conceptual coherence to Tullock's various particular lines of scholarship.

B. Tullock and Posner and their Contrasting Orientations. In his contribution for a Festschrift honoring Tullock, Charles Goetz (1987) observes that Tullock's scholarship in law and economics has been largely ignored, in contrast to the reception his scholarship has received in other fields. Tullock (1996: 1), moreover, concurred in Goetz's judgment when he noted that "I have been cast into the outer darkness . . . by the law and economics movement in the United States." In making his point, Goetz compares Tullock (1971) with Posner (1973). Goetz attributes Tullock's lukewarm reception among lawyers as largely a product of Tullock's informal and conversational style of presentation. Recognizing that Goetz wrote this from his vantage point as a professor of law in a premiere law school, I am in no position to challenge that claim. All the same, I think there is more to the differences in reception accorded to those works and their theorists. That difference partly reflects the ability of different conceptual formulations to enable other scholars to do the work they choose to do. Posner (1973) accomplished more than Tullock (1971, 1980a) in this respect. But why is that so? What lessons can be gleaned from this comparison?

Consider one of the several examples where Posner asserted a claim on behalf of legal efficiency and which Tullock (1980b) disputed. Consider the common law principle that railroads owed a duty of care to pedestrians only at crossings, whereas they always owed a duty of care to straying cattle. About this principle, Posner offered the gloss that it would be less costly for a pedestrian to choose a different path than it would

be for a railroad to watch continually for pedestrians. Posner further claimed that the reverse relationship would hold for straying cattle, for it would be more costly for a farmer to fence cattle than it would be for a railroad to keep watch. This gloss fits the efficiency rationale. But is that gloss warranted? Tullock claims that it wasn't. Perhaps walking along the railroad path might save a pedestrian only 100 m as compared with following the sidewalk. But what if that alternative distance were 1,000 m, or even longer? Tullock points out that Posner's empirical claim about relative costs is accompanied by no evidence about those costs. Even more, the cost of watching for humans and cattle are joint and not separable costs. Given that a railroad will be watching for cattle, the marginal cost of watching for humans is zero.

At this point we return to the unavoidable situation where the theoretical framework we use influences what we see in the first place. "Efficiency" is not something that is directly apprehensible. It is rather a conclusion that is drawn from a particular analytical model and with different models often leading to different conclusions. For instance, economists describe a competitive equilibrium as entailing the condition that price equals marginal cost. Cost functions are boundaries that separate what is possible from what is impossible. An average cost function, for instance, defines a boundary where it is impossible for cost to be lower but it is possible for cost to be higher. In recognition of this boundary quality, one might reasonably wonder why economists regularly presume that economic outcomes occur along the boundary and not at some interior position. The answer has nothing at all to do with observation, for it is impossible to observe what is truly the least cost manner of doing something. One might observe that some people produce in lower-cost fashion than other people without being able to determine the lowest possible cost of production. Rather what economists do is make the plausible claim that an individual proprietor would prefer to avoid waste in his or her operation because the proprietor owns the residual between revenues and expenses and transform this reasonable claim into a theoretical generalization.

Tullock's claims that deny the efficiency claims on behalf of common law are not evidentiary-based claims that can point to a failure to use lower-cost options. Tullock's claims are rather advanced in recognition that no evidence has been presented one way or another. In the railroad and cattle case, evidence would entail separately generated data pertaining to different ways of fencing cattle relative to different costs to a railroad of trying to avoid accidents. It may very well be the case that the cost of making finer determinations about costliness in such cases may exceed what people are willing to spend to make such a determination. A judgment will have to be rendered in the case all the same, simply because the case must be resolved in some fashion so that life can go on. This situation doesn't render the common law economically efficient by default, but rather renders the question impossible of being answered.

A famous problem in statistical decision theory involves a lady who claims that in tasting a cup of tea, she can tell whether the tea or the milk was put first into the cup (Neyman 1950). A judge must decide whether to accept or reject the lady's claim. To do this an experiment is designed and evidence generated, from which a judgment is made. With respect to law and economics, this setting is equivalent to asking whether or not the lady is an efficient oracle for determining how a cup of tea is made. Yet there is no way of making such a determination with perfect accuracy because the "truth" of the matter cannot be determined independently of the evidence and standard of judgment used to reach a determination. Errors of judgment will be unavoidable. The lady's claim might be granted when she truly can't tell the difference between the methods. It might also be rejected even though she can tell the difference. Furthermore, an increased effort to avoid one type of error will increase the frequency with which the other type of error is made.

In this setting, efficiency or accuracy is not a binary variable of yes or no but is a quantity that has the property of more and less. Many procedures for reaching a judgment are possible, and these procedures will typically differ both in their costliness and in their ability to avoid one or the

other type of error. Tullock's approach to legal efficiency fits fully within the framework of decision theory. Aside from accuracy and cost, there is also question of the standard of judgment and with higher standards of judgment typically involving more costly procedures. For instance, accuracy will increase as the lady is given more cups of tea to taste, but cost will also rise with the number of cups tasted. It is here where standards of judgment come into play. One judge might feel comfortable granting the lady's claim by invoking a 60 % confidence level, perhaps as expressed by a preponderance of evidence. Another judge might insist upon a 95 % confidence level, perhaps as expressed by overwhelmingly strong evidence. In these situations there is no God's-eye platform from which "truth" can be pronounced. Rather what exists are various decision procedures with varying ability to provide useful evidence and which differ both in their costliness and in their error-avoidance properties.

Tullock's approach to the cost and accuracy of judicial proceedings fits within this decision theory motif. For instance, where Posner analogizes the common law to a competitive market system, Tullock analogizes it to a socialist bureaucracy. There is something to be said in support of each analogy, while there are also things to be said against each of them. The common law system features competition among attorneys for custom and between attorneys at trials. Tullock argues that this system resembles an arms race with both cheap and expensive points of equilibrium and with the process tending toward the expensive equilibrium. On this basis Tullock favors the civil law procedure where judges and not lawyers are the dominant players. But judges are bureaucrats who are paid through tax revenues and not from clients who are seeking their services. Furthermore, law and politics are deeply entangled, as all legal systems are replete with public ordering where the private law principles of property and contract are hemmed in through various politically articulated requirements. Even arbitration, which entails far more private ordering than either common or civil law, requires the willingness of public officials to enforce the judgments that are reached in those proceedings.

Impact and Legacy

A scholar's legacy is, of course, something that will be determined with the passing of time. At the present time, the Goetz-Tullock appraisal of Tullock's reception within the Anglo-Saxon world remains reasonable. That appraisal reflects in good measure the continued predominance of static equilibrium as the core of economic theory. There are, however, signs that various forms of ecological and evolutionary theorizing are gaining momentum within economics. Should that momentum continue to build in the coming years, it is certainly possible that the process-oriented and substantive questions that Tullock addressed will rise within the attention spaces of law and economics scholars relative to formulations that address questions that pertain to models of static equilibrium.

Governance

Paul Dragos Aligica
 Mercatus Center, George Mason University,
 Arlington, VA, USA

Definition

“Governance” is a concept that has emerged to salience at the interdisciplinary interface of several fields relevant for law and economics. A typical governance situation involves not just formal institutions but informal ones, social norms and rules, law, legislation and economic incentives, regulations and enforcement, arbitration and conflict resolution mechanisms, preference aggregation procedures, values and perceptions, and path dependent elements. In the diverse literatures dealing with these phenomena, several major modes of using the notion of “governance” have emerged: governance as describing a recently emerging phenomenon transcending the traditional regulatory, administrative, and public/private choice interface functions of modern states; governance as a functional domain – structures and functions operating in relationship to commons, natural resources and specific collective goods production,

management and consumption processes; governance as a theoretical apparatus, a set of concepts, models, and theories aiming at analyzing regulatory, administrative, and public/private choice interface situations, including those depicted by the abovementioned literatures. The concept also applies to the related phenomena associated with the modern corporation and its (legal, political, and social) operational environment. The notion of “corporate governance” is, for instance, a typical example of how this concept is blurring the lines between the “public” and the “private,” between regulation and self-regulation, between markets, hierarchies, and networks.

Governance: A Multifaceted Motion

The concept of “governance” has emerged in the last several decades as an alternative mode of theoretically framing the complex political, economic, legal, and social mechanisms and processes associated to the collective decision making, regulation, and administration of political and economic systems, transcending the classical “markets” versus “states” and “public” versus “private” approach. At the same time, it is a way of describing all political and public administration processes and cases taking place in addition to, beyond, or outside of the state/government-centered structures and methods. That covers both the cases of complex modern large-scale advanced postindustrial democracies systems and the cases of groups, small communities, and societies that do not share the scale and complexity of the modern systems. The concept also applies to the related phenomena associated with the modern corporation and its legal, political, and social operational environment. The notion of “corporate governance,” is, for instance, a typical example of how this concept is blurring the lines between the “public” and the “private,” between regulation and self-regulation and between markets, hierarchies, and networks.

Thus, “governance” is by its very nature, a concept emerging at an interdisciplinary interface. A typical governance situation involves not just formal institutions but informal ones,

social norms and rules, law, legislation and economic incentives, regulations and enforcement, arbitration and conflict resolution mechanisms, preference aggregation procedures, values and perceptions, and path-dependent elements. A large literature (both positive-analytical and normative-prescriptive) has grown under this label with roots in political economy, law and economics, political philosophy, public administration, management studies, anthropology, sociology, and history. At the core of this exploding literature stands a large variety of “governance” forms and domains and their multiple facets, as framed using diverse theoretical lenses. This includes governance as a political theory concept, as a structure (architecture of institutions), as a process (the dynamics of functions), as a mechanism (procedures and decision rules), as a public choice intuitionism theory, as a strategy (actions related to control and institutional design shaping preferences and decisions), and as a normative ideal.

Due to its multifaceted nature and its versatility and traveling capacity from one discipline and intellectual tradition to another, the notion of “governance” is also increasingly assuming all the features of a typically “essentially contested” concept, gradually joining in this respect other key terms that form our political vocabulary such as “democracy,” “liberalism,” “government,” “politics.” “Essentially contested” concepts do not display a mere ambiguity about usage, about a core meaning, which could be solved using standard analytical methods, but reflect a deeper tension or disagreement about different configurations of theoretical, descriptive, and normative elements that are implicit in the usage of the concept by different schools of thought, disciplines, and intellectual traditions. These systems or configurations of ideas, which embed the concept in case, are sharing some elements – sometimes at all three levels, descriptive, theoretical, or normative – but not all of them, a fact which makes the disentanglement of the meaning of the concept in case always extremely difficult and contestable. When it comes to the concept of “governance” that means that the usual caveats applied to any encyclopedia entry

dealing with this special class of concepts, should apply to it as well.

In what follows, this entry will illustrate the potential of the family of perspectives gravitating around the concept, by focusing on three modes of using it. All are at the general and encompassing level, all are backed by solid literatures: (1) governance as describing a recently emerging phenomenon transcending the traditional regulatory, administrative and public/private choice interface functions of modern states; (2) governance as a functional domain – structures and functions operating in relationship to commons, natural resources and specific collective goods production, management and consumption processes; (3) governance as a theoretical apparatus, a set of concepts, models, and theories aiming at analyzing regulatory, administrative, and public/private choice interface situations, including those depicted by the above mentioned literatures.

The New Realities of “Governance”

The starting point of the first is the observation that a “new reality” has been created at both the national and the global levels: Globalization, competition, technological change, financial pressure, and increased demands due to changes in perceptions, preferences, values, and expectations put an increasing pressure of governments. A shift has taken place. The new conditions have generated a pressure to adjust the regimes centered on nation-states and on the hierarchical command and control arrangements based on Weberian bureaucracy and Wilsonian public administration. The typical national governmental structures are overextended, lacking capabilities and unable to administer, intervene and control as directly and as effectively as before. Because the state capacity of control diminishes, it has to adjust its modus operandi. A change of approach has to take place focusing now on indirect, negotiated influence, “outsourcing” or building partnership with the private sector and civil society.

Private actors and hybrid forms of organization become players in traditionally public domains, blurring thus the public-sector/private-sector

distinction. The retreat of government's control has encouraged an expanding role of civil society, a diminished view of the role of elected officials, an emphasis on political entrepreneurship, the pooling of public and private resources, and reliance on market or quasi-market discipline. Decentralization and de-monopolization has encouraged a variety of formal and informal hybrid public-private organizational forms, pluralist, multilevel, and polycentric arrangements. These changes have led to a move from politics, hierarchies, and communities to markets; from provision to regulation; from public authority to private authority; from big government to small government; and from regulation based on command and control to flexible and diverse forms of regulation in which self-regulation is an important element. The overall result has been the growth of "governance without government." Given these developments, "governance" has come to indicate an entire range of public and semi-public mechanisms and institutions for implementing policy, working either as alternatives to "government" or in conjunction with it. The boundaries between the public, private, and voluntary sectors have changed and with that the very role of the state (Peters and Pierre 1998).

A very telling metaphor recurrently used to portray these phenomena is based on the distinction between "rowing" functions (service provision, taxation, redistribution) and "steering" functions (rulemaking, monitoring and enforcement). Expressed in these terms, the point is that a shift has taken place. Initially, states were bent on command and direct provision, insisting on doing both the "rowing" and "steering." Now states are increasingly focused on "steering," while markets, the voluntary sector, and nonprofit civil society do the "rowing." The literature is not displaying a unitary interpretation; there are alternative modes of understanding the "new reality." For instance, on the one hand, there is the "hollowing out the state" thesis whereby authority is shifting either "up" to markets and transnational institutions or "down" to local governments, business communities, and nongovernmental organizations. On the other hand, there is the thesis that the state has in fact reasserted its authority by

shifting its focus at the meta-level towards "regulating the mix of governing structures such as markets and networks and deploying indirect instruments of control," the notion of meta-governance (Levi-Faur 2012, p. 36).

As noted, the developments outlined above have generated a robust literature. One could appreciate the publication of volumes like *The Oxford Handbook of Governance* (Levi-Faur 2012) and *The Oxford Handbook of Public Management* (Ferlie et al. 2007) as one of the most significant indicators of the status and impact of that literature. The first volume charts the "new reality" created at both the national and the global levels as the role of the state and the boundaries between the public, private, and voluntary sectors have changed. It illustrates how these themes are at the core of both the academic and applied agenda, and it points out to some ways of theorizing, describing, and analyzing them. The second volume takes the applied angle and documents the emergence to salience of themes such as proactive administration, administrative responsiveness and responsibility, street-level bureaucracy, citizen participation, public-private partnerships, decentralization, hybridity, contracting, and NGOs.

Governance as a Functional Domain

The second mode of illustrating the "governance" perspective is as the study of institutional arrangements dealing with specific social dilemmas of collective action, in particular circumstances defined in functional, local, and contextual terms. Its most salient application is regarding the commons, natural resources, and specific collective goods production, management, and consumption processes. The contribution of 2009 co-recipient of Nobel Prize in Economics, Elinor Ostrom, is illustrative, her "governing the commons" work being a source of inspiration and considered as paradigmatic in this respect (Ostrom 1990).

From this perspective, the notion of "governance" is a term associated to a set of institutional and procedural solutions to collective action situations generated by the collective production, financing, and consumption of goods and services

that have particular properties that diverge from the private goods ideal (in terms of excludability and jointness of consumption) (Ostrom and Ostrom 2004). A “commons” is a good that is shared by multiple users and has two properties: rivalrous and nonexcludability. The use of a commons by one user changes the state of the commons and has implications for the preferences and behavior of other users, who change their behavior and overuse or deplete the resource, leading, without intention, on the long run, to a decrease of the welfare for the entire group: This is the so-called “tragedy of the commons.” It is by definition a collective-action problem: The incentives defining a situation induce a divergence between the individual and collective logic, generating a rush to enjoy/use/consume the resource. Thus, the commons is predicted to deteriorate, affecting the welfare of all the commons users.

E. Ostrom and her team of researchers not only built an extensive database and a theoretical and methodological apparatus to study how people deal with such situations, but also engaged in extensive fieldwork examining particular case-studies of governance systems of fisheries, irrigation systems, pastures, forests, etc., in both developed and developing countries, at various levels and scales. At the core of the agenda was a demonstration that the “tragedy of the commons” could be and has been avoided in many cases, without making use of state-based mechanisms and enforcement. Ingenious institutional arrangements and social norms were created and enforced, leading to viable and resilient governance structures. The “governing the commons” research program has thus shown that “governance” is possible outside the state-market dualism that dominated mainstream policy analysis. It illustrates empirically and analytically not only that community-based governance may be a viable alternative, but also that governance functions may be operationalized through diverse institutional forms. Hence the notion of “governance” has come to be associated to the notion of “institutional diversity.” In addition to that, a significant part of the work was focused on the conditions and mechanisms motivating the commons users to behave cooperatively. E. Ostrom identified a set

design principles, noting that they characterize robust institutions used by communities managing common-pool resources such as forests or fisheries. With that, the notion of “governance” has also come to be associated to the notion of “institutional design.”

Last but not least, the “design principles” demonstrated the possibilities for self-governance of human communities and the ability of people to bottom up design and manage solutions to social dilemmas. The Ostroms’ research program exploring the governance of the commons has thus to be seen as part of a larger program having an assumed applied and normative dimension: “What is missing from the policy analyst’s tool kit – and from the set of accepted, well developed theories of human organization – is an adequately specified theory of collective action whereby a group of principals can organize themselves voluntarily to retain residuals of their own efforts” (Ostrom 1990, p. 24).

Governance as a Theoretical Apparatus

The third mode of using the concept of “governance” is precisely in connection to this theoretical toolkit. “Governance theory” is in this respect the range of conceptual and theoretical instruments available for the study of the phenomena identified and described above. From this perspective, “governance” refers to a description of “governance phenomena” (as social coordination, cooperation, and institutionalization) as seen through the lenses of this theoretical apparatus. It is a dual relationship. Theoretical lenses lead to a specific description and diagnosis of governance problems. While the problems, thus defined, entail for their analysis and solutions, the logic and social mechanisms implied by the toolkit. Most of the components of the toolkit have origins in economics: public choice, industrial organization, institutional theory, applied game theory, etc.

The theory of private and public goods, as already suggested above, offers a very effective illustration in this respect: Because the nature of goods determines the practicality of the various institutional structures meant to produce, finance, distribute, and consume these goods, a typology

of goods is a first step in understanding institutional diversity. Hence, a governance theorist approaches institutional arrangements as driven by a functional structure shaped by the nature of goods or services that those institutions are supposed to satisfy. Thus, a typology of goods (based on the “exclusion” and “jointness of use or consumption” dimensions, sometimes further elaborated in game theoretical forms) helps identify typologies of institutional forms. At their turn, the typologies of institutional forms help chart and analyze governance situations. This is the strategy advanced, for instance, by E. Ostrom and V. Ostrom (2004) or by 1986 Nobel Prize in Economics, James Buchanan (1967).

In a similar way, one may use transaction cost analysis, on the lines pioneered by Ronald Coase (1991 Nobel Prize in Economics) and further elaborated by O. Williamson (2009 Nobel Prize in Economics co-recipient). The logic is similar. The diverse nature of the transactions people have to engage into and especially their associated costs (search, monitoring, enforcement etc.) determine the practicality of the various institutional structures meant to deal with those transactions. (Coase 1992; Williamson 1979) Hence, a typology and analysis of transactions and of the costs associated to them is a first step in understanding institutional structure, function, and diversity. At its turn, the typology of institutions helps chart and analyze governance situations.

The list may go on: externalities, agent-principal, rent seeking, asymmetric information are all part of the catalogue or toolbox of the governance theorist or analyst. It is a modular toolkit which has a double function: On the one hand, it offers a vocabulary and thus the lenses to identify and describe governance situations, and at the same time, it offers analytical instruments to explain the social mechanisms and processes in place or to suggest such mechanisms and structures as governance solutions to the problems thus diagnosed. In this respect, it has strong connections with mechanism design theory (2007 Nobel Prize in Economics for Leonid Hurwicz, Eric Maskin and Roger B. Myerson) – an approach that uses “reverse game theory,” which starts with a desired function or objective, and tries to

identify and reconstruct the governance and institutional mechanism which may be able to achieve that specific objective or realize that functional solution (Maskin 2008). As such the “governance” approach assumes strong and unequivocal normative and applied level dimensions.

Government

Walter E. Block

Joseph A. Butt, S.J. College of Business, Loyola University New Orleans, New Orleans, LA, USA

Abstract

The institution of “government” is perhaps more debated among philosophers, political scientists, economists, historians, and other

social scientists than any other. In order to give a comprehensive assessment of this concept, I will offer several perspectives on it.

Definition

Government is a criminal gang with a lot of good public relations, so much so that most people think it has legitimacy

The Theocratic

In this vision, the king is the head of government and is also the leading religious figure. Sometimes, this type of emperor is actually God himself. As owner of the kingdom, literally, he is the unquestioned master of not only every stick, blade of grass, and other property in his realm but also the people in it. They are in effect his slaves; he is their master. His authority is unquestioned, both from the religious and secular perspective. One need not spend too much time criticizing this form of government. How can it be proven that any given individual is actually God or his chosen spokesman? Why is it justified that it is from this particular family that kings, queens, and princes emanate? Typically, this is based on success in war, but any justification for this process must rest on the unproven contention that “might makes right.”

The Democratic

Here, at least in pure form, the government is elected by the governed, and all decisions are based upon majority rule. The franchise might be broad or very narrow (e.g., limited to white, male property owners). The inclusive version of this system enjoys wide support. Most countries in the so-called civilized world engage in this political form. According to Winston Churchill, “democracy is the worst form of government except for all the others that have ever been tried.” But there are problems here. For one thing, Hitler, no popular figure, came to power

through a completely democratic process, not via a coup d'état. (Of course, it cannot be denied that he remained in power by abrogating the democratic system.) One is tempted to conclude from this one fact, “so much for democracy.” But this is only the tip of the iceberg, for there is such a thing as “the tyranny of the majority.” Just because a majority of the electorate prefers one candidate or policy over another does not guarantee he or it is justifiable. In many southern towns in the United States in the nineteenth century, a majority of the people might well have voted to lynch all black people.

The Republic

This form of polity allows for democracy but is subject to a constitution. That is, the society can vote alright, but it cannot cast a ballot for anything and everything. For example, some things cannot be determined by majority vote, such as should a certain minority of people be eliminated. This seems like an improvement over pure democracy, but it all depends upon how good the constitution is and whether or not it is followed. For instance, the US constitution allowed for slavery; the majority need not have voted to enslave black people: the constitution already allowed for that. Another example was the constitution of the Soviet Union. It protected all sorts of minority rights. But this relatively splendid document was all but ignored.

What have libertarians had to say about government? I pursue this question since this philosophical movement has some interesting and important things to say about this institution. Four different versions of libertarianism can be identified in terms of their vision of proper government. They are as follows:

1. Anarcho-capitalism
2. Minarchism
3. Classical liberals, or Constitutionalists
4. Free market supporter

Libertarianism is predicated upon two basic building blocks: the nonaggression principle

(NAP) and private property rights based upon homesteading. The first maintains it is improper to threaten or initiate violence against an innocent person or his property. The second is a theory as to how just property titles come into being. They start with self-ownership, continue with the mixing of one's labor with land and other natural resources, and conclude with any voluntary means of title transfer, such as buying and selling, gifts, and gambling.

Anarcho-Capitalism

The anarcho-capitalist version of libertarianism cleaves most closely to these principles. It brooks no compromise, none whatsoever, with private property rights and the NAP. That is, it concludes that government is a per se violation of rights. All governments do two things: they tax their subjects and forcefully prevent other entities from competing with them, within their geographical territory. But taxation is theft. People did not agree to be taxed. Any "social contract" to the contrary is a figment of the statist's imagination. Taxes are not akin to club dues. The latter rises from contract, not the former. Thus, for the anarcho-capitalist version of libertarianism, government is not merely akin to a robber gang, but indeed takes on that exact description. The only difference between it and a bunch of outright thugs is that the state has legitimacy in the minds of most people and that gangsters do not. So similar are the two, apart from the far better public relations of the government, that when a criminal engages in a crime such as murder, rape, and theft, he can be said to have undertaken a governmental act (apart from the seeming legitimacy of it).

The scholars most closely associated with this perspective are Murray N. Rothbard, Lysander Spooner, and Hans-Hermann Hoppe.

Minarchism

The libertarian perspective consistent with the principles of this philosophy to the second greatest degree advocates minimal state government and is called minarchism. Here, the government is indeed a legitimate institution, but the sole function of the state is to protect the persons and property rights of its citizens. To that end there are

three and only three legitimate governmental institutions: One, armies to protect domestic inhabitants against foreign aggression. (Not to become policeman to the world; not to engage in imperialistic ventures here, there, and everywhere; solely for *defense*.) Think in terms of a gigantic, ferocious, and very powerful Coast Guard. The second justified institution is police, to protect us from local violators of the NAP: to stop murderers, rapists, thieves, etc. (not to arrest victimless criminals for "crimes" involving consenting adult behavior such as pertaining to drugs, pornography, prostitution, gambling). Third, courts to determine guilt or innocence of those accused of real crimes and to address contract disputes. Minarchists strictly limit government to these three institutions.

Key contributors to this perspective are Robert Nozick, Ayn Rand, and Ludwig von Mises.

Classical Liberals, or Constitutionalists

Next in the libertarian pantheon in terms of consistency to principle are the Classical Liberals or Constitutionalists. To the three functions of government, advocates of this version of libertarianism would add a few more: dealing with communicable diseases and storms and floods and providing "public goods" such as roads and utilities like gas, electric, water, sewage removal, etc. Some in this category would include anything mentioned in the US constitution, such as post offices and coinage. Ron Paul is perhaps the most famous person connected with this viewpoint.

Free Market Supporters

Here, there are lots of compromises: health, education, welfare, externalities, antitrust policy, and monetary crankism (e.g., rejection of the gold standard). So much so that there are questions as to whether or not this viewpoint can be considered libertarian at all. On the other hand, people associated with this perspective are staunch advocates of the free enterprise system and adamantly oppose government incursions such as rent control, minimum wages, tariffs, corporate welfare, crony capitalism, and entry restrictions for business. They favor the profit and loss system. Those

associated with this point of view include Milton Friedman, Friedrich Hayek, and Rand Paul.

I now move to a discussion of anarcho-capitalism, the purest form of libertarianism, since its indictment of the government is the most accurate. That is, the state really is an organized means of NAP violation. It is the only institution in all of society which may legally initiate violence against innocent people. As such, it deserves intensive analysis, in any effort to understand what government is all about.

Let us start off with Rothbard (1977) who avers that it is important that any libertarian

... hates the existing American State or the State per se, hates it deep in his belly as a predatory gang of robbers, enslavers, and murderers... the State – *any* State – is a predatory gang of criminals... the radical (libertarian) regards the State as our mortal enemy, which must be hacked away at wherever and whenever we can. To the radical libertarian, we must take any and every opportunity to chop away at the State, whether it's to reduce or abolish a tax, a budget appropriation, or a regulatory power. And the radical libertarian is insatiable in this appetite until the State has been abolished...

There are those who would quarrel with such an analysis and maintain that the government is really a voluntary organization, like a club. And, just as in the case of the golf, or tennis, or chess club, every member must pay his dues. In this case that would be taxation. But Schumpeter (1942, p. 198) puts paid to this excuse for brutality: “The theory which construes taxes on the analogy of club dues or of the purchase of the services of, say, a doctor only proves how far removed this part of the social science is from scientific habits of mind.” The point is there is simply no contract, “social,” or otherwise that binds people together. Only a very few people signed the declaration of independence. How can it be binding on an entire populace?

But did not three-quarters of the states ratify the national government in the case of the United States, by a majority in each case? This cannot be denied. But how does that bind the people in the states that did not ratify this document? How does it obligate those who did not vote or voted against the proposal? No rational court would hold a person responsible for a commercial contract

to which he did not agree, just because others, even many others, did so.

Suppose a slave master allows his property to vote on overseer Goodie, who will only beat them once per week, and overseer Baddie who will do so three times per day. The slaves opt for the former. Does this mean these poor unfortunates have agreed to be slaves and that they agree to have Goodie whip them? Of course not. Spooner (1966[1870]) is justly famous in libertarian circles for making just this point. He also disposed of the argument that tax compliance demonstrates agreement with government overseers. We also pay the highwayman when he holds a gun on us. This hardly provides evidence that our “transaction” with him is a voluntary one, and unless it is the ethical case for the state has no foundation.

What about the following argument: “If you don’t like it here, under this government, you are free to leave. The fact that you stay indicates voluntary agreement with these institutional arrangements.” Stuff and nonsense. One difficulty with this is that it argues in a circle. It presupposes the truth of that very thing that is under debate, namely, that the government has a right to kick people out of “its” territory if they do not comply with its onerous regulations. If we jettison this basic unproven premise, then there is no case for inviting people to “leave” who object to statist depredations. Another difficulty is that there were people living on the territory taken over by the government before it was set up. This is necessarily so. There had to be people in existence to set up a government before it was operational. Thus, these people were there *before* the advent of the government. They could with as much justification say to those in the process of forming a government: “If you don’t like it here, under our present state of free market anarchism, you are free to leave.” Why must those who object to this obnoxious institution be the ones who must leave, on logical grounds?

Let us attempt to further “hack away” at this truly evil type of organization. It is said that the reason we need a government is because two individuals, or groups of people, will fight each other without such an institution, and, if allowed, this would create chaos. Or bullies would prey on

the weak. There are great difficulties with this view. First of all, as a matter of historical fact (Rummel 1994), governments have murdered more than 150 millions of their own citizens in the last century, and this is apart from the wars they have fomented with each other. And this statistic does not even include some 40,000 people slaughtered on US government highways (Block 2009). Gangsters and bullies are simply not in the same category. Secondly, a logical implication of national government is world government. If we need a national government because people in that territory will fight with each other, then we need a world government since national governments will (and most certainly have) fight with each other. The problem with world government is of course that there will be nowhere to run when and if such an institution turns totalitarian. But if world government is rejected, so, then, must the same fate await national government, since there is a perfect analogy between the two cases.

Here is yet another attempt to justify the unjustifiable: the government gives us goods and services in return for the taxation it imposes on us. This, too, cannot be denied. The state provides a myriad of goods and services, ranging from battleships to postal service, from welfare to food stamps, from bailouts to Detroit, to Wall Street, and to numerous points in between. But suppose a philosophical mugger who is willing to engage in discourse were to hold up an innocent man. The latter objects on the ground that the robber is not providing any goods or services, whereupon the thief agrees with his victim, amends his evil ways, and offers him the services of a smile or a snarl, and, also, a paper clip or a rubber band. The point is, it is entirely irrelevant whether or not the private or governmental burglar offers his prey anything in return for his depredations or not. The only relevant issue is if the citizen did *agree* to the interaction or not, and, as we have seen, not only is there no evidence that everyone unanimously agreed, but also there *could not* have been any such occurrence. For, if it did, if, that is, all the citizens welcomed the government, that would be a logical contradiction. For government is defined as that institution about

which everyone most patently *did not* agree. If there were an organization to which all participants voluntarily subscribed, it would no longer be a government! Rather, it would be some sort of private institution. A very large one, but similar in all essential regards to a business firm. For the latter embodies “capitalists acts between consenting adults” in the felicitous phraseology of Nozick (1974, p. 163).

Government Failure

Giuseppe Di Vita
Department of Economics and Business,
University of Catania, Catania, Italy

Abstract

The analysis begins from the origin of the concept of market failure and continues with an explanation of the reasons why a

measure of political economy could worsen market allocation and the level of social welfare. Mention is made of the differences between Europe and the United States regarding the weight of the State in the economy and of the efforts made by research to give a quantitative measure to government failure.

Definition

Government failure occurs when a measure of economic policy or the inactivity of the government worsens the market allocation of resources reducing economic welfare.

Government Failure

From a reading of the first few chapters of textbooks of *Principles of Economics*, we have learned that under the assumption of a perfect competitive market, for each good (or bad) exchanged, the economy achieves its maximum level of welfare as a result of the Smithian theory of the “invisible hand” (Smith 1776). This means that in such a Pareto-optimal situation, there is no room for economic policy measures that, if adopted, may only constitute an obstacle to the proper functioning of the market.

Despite this unlimited confidence in the market virtues, the same Adam Smith was forced to recognize the limits of the market, regarding national defense, justice, and public services (i.e., waterworks, hospitals, schools, roads, etc.), for which there is no profit in producing at an individual level, because the costs are always greater than the revenues (Smith 1776). Although one of the fathers of the modern economic theory recognized the limits of the market, the dominant view, up until the 1940s, was that the government should not interfere with the market to modify or change market allocation or income distribution.

The Great Depression started in the late 1930s and the subsequent Keynesian theory (Keynes 1936) was further instrumental in destroying the myth of the free market. After the Second World War, the economic theory started to consider than

before the existence and causes of market failure more seriously (Bator 1958) and saw the need for some government intervention, the so-called visible hand (Chandler 1977), to improve market allocation and raise the level of social welfare.

During the second half of the last century, the broad consensus regarding the positive consequences of adopting economic policy to correct the effects of market failures on economic welfare Coase (1964) introduced into the economic literature the expression “government failure,” as opposed to “market failure,” to express some concern about the continual assumption of Pareto-improving consequences of economic policy measures (Posner 1969, 1974). (Ronald Coase (1964) agreed with the approach which evaluated the effects of economic policy measures comparing regulated industries with industries not subject to regulation, although this approach cannot be followed because it is difficult to find industries that are comparable regardless of the degree of regulation.)

Coase drew inspiration from the talk of Professor Roger C. Cramton, a law scholar, held in Boston during the Seventy-Sixth Annual Meeting of the American Economic Association: Cramton stated that lawyers “. . . focus on the fact that public officials and tribunals are going to be fallible at best and incompetent or abusive at worst. . . .” Coase (1964) remarks that this statement is completely opposed to the assumption that the economists make about the government. In the economic theory, the government is seen as a benevolent planner who wants to correct the defects of the invisible hand, to improve market allocation, and to raise the level of welfare. The opinion of the government expressed by Professor Crampton would probably have been considered provocative, but for the economist, it was an alarm bell underlining the necessity to rethink the assumption about the government bodies and the impact of economic policy measures on the level of welfare. (In general, about the measure of economic policy, we can report the words of Milton Friedman (1975): “. . . The government solution to a problem is usually as bad as the problem and very often makes the problem worse. . . .”)

Moreover, Coase (1964) emphasizes the inability of the government to supply an immediate answer to the changes in economic conditions and the crucial role of “detailed knowledge” (or information) of the economic phenomenon addressed by a measure of economic policy, as an ineluctable condition of government intervention. (Winston (2006) has recently affirmed that government failure “. . . arises when government has created inefficiencies because it should not have intervened [in the market] in the first place, or when it could have solved a given problem or set of problems more efficiently, that is, by generating greater net benefits. . .”; such a definition emphasizes the inability of the government to improve market allocation.)

It is possible to affirm that a government policy is worth adopting in the presence of a market failure that is a source of not negligible social costs (see Datta-Chaudhuri (1990), Krueger (1990), Wallis and Dollery (1999, 2001), and Wiesner (1998) about the policy measures adopted in developing countries, since the 1960s, as sources of economic inefficiency which worsen the welfare level) where the government policy is at least improving market performance and efficiently correcting the market failure and optimizing the economic welfare (for normative economic theories of government failure, see Dollery and Worthington 1996).

The first possible source of government failure is the dynamic nature of an economic process such that the government in charge cannot commit itself for future measures which will be adopted by the subsequent government. (The dynamic nature of the economic process makes it necessary to consider the discount rate in the analysis: this is a task that we leave to future and more detailed analysis.) Stiglitz (1998) offers the example of hydroelectricity plants to produce electricity which need to be subsidized for a period of time longer than the duration of the legislature, while the hydroelectricity industries have no guarantee that successive governments will leave unaltered the subsidies and the legislation. (The inability to make commitments causes another set of inefficiencies: the cost of creating next-best credibility-enhancing mechanisms. While those in the

government at one date cannot commit future governments, they can affect the transaction costs of reversing policies (Stiglitz 1998, p. 10).)

The economic policy measures worsen market allocation whenever there is imperfect information between the policy maker and the private parties involved. Imperfect information may represent an obstacle to improving Pareto efficiency, if the policy maker does not have access to all the relevant information to adopt the correct policy measure or establish the magnitude of the measure (e.g., the amount of the rate of taxation).

The third source of government failure is the so-called destructive competition, a process that occurs in the presence of imperfect competition. Firms can get ahead not just by producing a better product at lower costs but also by raising the costs of their rivals (Salop and Scheffman 1983). Destructive competition is a zero-sum game where the profit of one is at the expense of another (see, e.g., the political games, with positions to be won or lost). This means that under the imperfect competition market structure, the liberalization of the market or the inactivity of the policy maker (Orbach 2013), as a result of a rational choice, determines the achievement of a suboptimal level of social welfare.

Another source of government failure is uncertainty about the consequences of policies: this may be due, as in the case of economic policy measures taken under asymmetric information, to the inability to predict the future impact of economic policies adopted now. A lesson we learned is that to be effective, economic policy measures should have well-defined objectives to achieve; otherwise, the measures taken by the government without a clear and precise statement of the objectives to be pursued and of the resources to meet them are just a way to leave unchanged the allocation of resources and the distribution of income (Cramton 1964). This means that some cases that may be attributable to the concept of government failure are just from the point of view of social welfare, because the government policies worsen market allocation but satisfy the real will of the policy maker to protect some established interests, without displeasing public opinion.

Finally, the last point we address is that government policies may be constrained in their action and worsen welfare due to the complexity of the economic measures that are hard for public opinion to understand, so Stiglitz (1998) empathizes the “simplicity constraint” in economic policies. Simple policies are easily explained to, and approved by, public opinion.

In a more interdisciplinary environment, considering laws, institutions, and economics, the theory of government failure has recently been enriched, affirming that it may also be due to the inefficient designing of rules for the economy that may be excessively specific (i.e., standard), too broad, conflicting, and unfair (Dolfsma 2011). (In general, on inefficient regulation as a source of government failure, see Posner (1974).)

The theories of government failure have played a different role in the United States and in the Old Continent because in the former they have been used to justify the limited adoption of economic policy measures and a reduced role of the state within the economy. In Europe, the limits of government action have been used to justify a reduction of the weight of the public sector in the economy (Vickers and Yarrow 1991).

Despite the differences between Europe and the United States in the role of the state in the economy that can be measured by the tax burden (Romer and Romer 2010), the government follows the business cycle in its policies because during crises, it is forced by public opinion to adopt stronger measures to curb the crisis (Rajan 2009), while during periods of prosperity, it is more prone to pander to the desire of firms for freedom.

Winston (2006), basing his theories on an empirical research limited to antitrust, monopsony policy, and economic regulation to curb market power, so-called social regulatory policies to correct imperfect information and externalities, and public production to provide socially desirable services, reached the conclusion that government intervention in markets has either been unnecessary or has missed significant opportunities to improve performance. (For recent development of the theory of “government failure,” see Mitchell and Simmons (1994) and Winston (2006).)

The economic policy measures to correct the limitations of markets have played a significant role in economic history (Datta-Chaudhuri 1990) and will probably continue to be useful in the future, but to improve market allocation, the policy maker should be aware of the limits of the “visible hand” (Winston 2012).

heritage, and constitutional design. The lion's share of empirical work has employed measures of government quality based on perceptions. A debate exists about the convenience of conflating government quality with institutional quality. To measure institutional quality, it may be more advisable to generate measures or indicators which capture the extent to which institutions actually constrain governments.

Definition

Government quality is a multidimensional concept. Government quality is said to improve if the public sector does not distort the proper functioning of the private sector (respects property rights, does not overregulate), is an efficient administrator (low corruption, less bureaucracy, high tax compliance), provides public goods (education, health, infrastructures, etc.), and, finally, allows for and protects political freedom.

Government Quality

Over the years, economists have come to identify government or institutional quality as a fundamental cause of economic development. Early on, North and Thomas (1973) argued that the establishment of private property rights was instrumental for the rise of the West since the middle ages. Inspired by this insight, a great deal of scholarship has empirically explored the link between institutional quality and development (most notably Hall and Jones 1999; Acemoglu et al. 2001; 2002; Rodrik et al. 2004).

Growth-promoting institutions have at least two features: they must enforce property rights for a broad cross section of society so that all individuals have an incentive to invest, innovate, and take part in economic activity. And they must furnish some degree of equality of opportunity in society, including equality before the law (so that those with good investment opportunities can take advantage of them), and equal access to health and education (to promote human capital and to account for the fact that entrepreneurial initiative

Government Quality

Abstract

A growing body of work in economics has pointed towards the crucial importance of government quality for economic development. A major issue emerging in related empirical work has been the need to account for the confounding influence of other factors as well as the presence of reverse causality or the likelihood that development itself may facilitate governance. The potentially key role of government quality in explaining international differences in economic development has led many scholars to try and identify those factors that determine it. This research effort has brought forth the role of numerous variables including social heterogeneity, cultural

may be randomly distributed in the population and as such be independent of the distribution of property rights to existing resources) (Acemoglu et al. 2005).

A major concern which emerges when attempting to calibrate the impact of government quality on development is the issue of reverse causality or, in other words, the expectation that development facilitates institutional quality. In this vein, it has been argued that economic development makes better quality institutions more affordable (Islam and Montenegro 2002) and will tend to create a demand for better government (La Porta et al. 1999), perhaps because of income's positive effect on education, literacy, and depersonalized relationships (Treisman 2000). To deal with reverse causality, scholars have employed various instruments of government quality. Arguably the most notable has been settler mortality in the New World proposed by Acemoglu et al. (2001, 2002). They argue that in those colonies with high indigenous population densities where the disease environment was inimical to mass European settlement, extractive institutions, with few limits on the capacity of the state to expropriate individuals, were set up. And these institutions persist over time, not least because of the interest of the extractive elite to maintain their privileges. Conversely, in those colonies which were sparsely populated where, moreover, the disease environment was more benign, mass European settlement occurred leading to demands for good quality government (c.f. Sokoloff and Engerman 2000). Cross-country empirical work based on settler mortality suggests that government quality is a key factor explaining international differences in economic development, even trumping the direct effect of geography and trade (Rodrik et al. 2004).

The robustness of these finding has not gone unchallenged. On the one hand, the quality of the mortality data has been the subject of some debate among scholars (Albouy 2012; Acemoglu et al. 2012). On the other, it has been argued that the pattern of European settlement may have influenced growth through other, more fundamental, channels, namely, human capital. Thus, European colonizers took with them their human

capital, and in those colonies which were more extensively settled, these human capital endowments enhanced both institutional and productive capacities leading to stronger economic development (Glaeser et al. 2004).

Notwithstanding these qualifications, and based on theoretical and empirical work pointing towards a key role of institutions for the wealth of nations, scholars have tried to identify those factors that determine institutional quality, beyond the level of economic development itself and initial conditions framed by climate and factor endowments. In particular it has been variously argued that government quality may be determined by a range of variables which include inter-personal income inequalities (You and Khagram 2005; Glaeser et al. 2003; Sonin 2003), ethnic heterogeneity (Alesina et al. 1999; Glaeser and Saks 2006; Alesina and Zhuravskaya 2011), and ethnic group inequalities (Baldwin and Huber 2010; Kyriacou 2013). In addition, international differences in government quality may be due to cross-country cultural differences (Fisman and Miguel 2007; Licht et al. 2007) which may be partly the result of different religious heritages (La Porta et al. 1999; North et al. 2013). Government quality may also be responsive to constitutional design including electoral rules and government systems (Persson et al. 2003; Kunicová and Rose-Ackerman 2005) and the degree of fiscal and political decentralization (Fisman and Gatti 2002; Enikolopov and Zhuravskaya 2007).

Quantitative work in law, economics, political science, and business administration has employed government quality indicators from a range of sources. These include the World Bank's Worldwide Governance Indicators, Transparency International's Corruption Perception Index, the World Economic Forum's Executive Opinion Survey, the International Country Risk Guide (ICRG) published by the Political Risk Services Group, and several indicators elaborated by Freedom House and the Fraser Institute. Because of their country coverage and comparability over time, many experts have relied on indicators from the ICRG – available since 1984 – as well as the Worldwide Governance

Indicators, available since 1996. The ICRG data are based on in-house expert assessments of different dimensions of government quality including government stability, contract viability or expropriation, corruption, law and order, democratic accountability, and bureaucratic quality.

Unlike the ICRG indicators which are derived from a single source, the Worldwide Governance Indicators are obtained from a host of perception-based sources, including the ICRG and the other sources listed above. The Worldwide Governance Indicators measure government quality across six dimensions: (1) voice and accountability, (2) political stability and the absence of violence, (3) government effectiveness, (4) regulatory quality, (5) the rule of law, and (6) control of corruption. A key feature of the indicators is that all country scores are accompanied by standard errors which reflect the number of sources available for a country and the extent to which these sources agree with each other (Kaufmann et al. 2010). It has been pointed out that the indicators measuring the last four dimensions are very strongly correlated and, as such, they may be measuring the same thing (Langbein and Knack 2010). As a result, it makes sense to combine these four into an aggregate indicator in empirical work. Moreover, it may be useful to view the first two dimensions as contributing towards the latter four.

There is some debate about conflating institutional quality with government quality. According to Douglass North (1991, p. 97) “institutions are the humanly devised constraints that structure political, economic and social interaction.” From this perspective, institutions are constitutions and other laws, and the test of good institutions would imply the examination of how such constraints improve social welfare. Because empirical work has tended to equate institutional quality with government quality, scholars have measured the former by way of the perception-based indicators reviewed above. But government quality indicators typically measure outcomes rather than institutional constraints per se, and objective measures of institutional constraints are typically uncorrelated with measures of government quality (Glaeser et al. 2004). However, empirical efforts relating de jure institutional constraints with

social outcomes are likely to be undermined by the possibility that the measures or indicators used may not capture the extent to which constraints are actually binding (Voigt 2013).

Greece: Ancient Greece

Michel S. Zouboulakis
Department of Economics, University of
Thessaly, Volos, Greece

Abstract

The Ancient Greek miracle is the synthesis of institutionally constrained free citizens seeking for their personal improvement within a democratically evolving law structure which guarantees public interest and social justice.

Definition

What we call ancient Greece was actually a large number of dispersed and independent city-states with a common language, religion, and social customs and yet with quite distinct political, social, and economic institutions. Chronologically, what we call Ancient Greek world extends from the eighth century BC to the second century AD. Geographically, the Ancient Greek world covered parts of Southern Italy and Sicily in the west, as well as the entire coast on the other side of the Aegean and the Black Sea, and many other parts of the Mediterranean, including North Africa, Southern France, and Spain. Our purpose here is to focus on a restricted part of Ancient Greek social and economic institutions, saying the minimum about the political institutions and nothing about the informal ones, meaning the values and social norms which shaped this glorious era of the western civilization.

Population and Citizenship

Cities were organized around a well-defined geographical center, and their population size varied from 250,000 in fifth-century Athens to 3,000 in the city-state of the island of Aegina. A common characteristic among all Greek cities was that not all the inhabitants were recognized as citizens with full political rights and civil duties. In general, citizens were free males above the age of 18, having completed their military duties. But not all adult free citizens, even if they were born in the city, had full citizenship. Noncitizens who were born free or were freed in their lifetime were often called and had military and tax obligations. An important part of every Greek city consisted of slaves, in an analogy (very different from city to city) one citizen for every two or three slaves. Social stratification differed from one city-state to another, although there were many common characteristics. In Athens, Solon introduced his institutional reforms in 594 BC, based on the division of citizens according to their income. Citizens, and therefore their obligations toward their city, were defined according to their

production: the *pentakosiomedimnoi* producing more than 500 *medimnos* (approximately 260,000 lit.); the *ippeis*, producing more than 300 *medimnos* or 156,000 lit.; the *zeugitai*, with more than 200 *medimnos* or 104,000 lit.; and finally the *thetes*, with less than 200 per year. Among these four property classes, the poorest had limited public rights; the *thetes* could vote in the Assembly but were excluded from public office. The richer classes provided the main military effort, as cavaliers (*ippeis*) or as heavily armed foot soldiers (*hoplites*). The situation in Sparta was different. Descendants of Spartan citizens got full citizenship at the age of 18, having received a proper military education called *agoge*. Other inhabitants were the *perioikoi*, who were free to live in Spartan territory but were noncitizens, and the *helots*, the state-owned serfs (Glötz 1928; Finley 1964; Cartledge 1993; Sakellariou 1999).

Political Institutions

Politically, the majority of Greek cities were ruled by aristocracies, oligarchies, and tyrannies in the eighth, seventh, and sixth centuries and oligarchies and democracies in the fifth and fourth. In Corinth, Argos, Sparta, Thebes, and many other cities, oligarchy was based on property. Aristotle described four types of oligarchy from the most autocratic cities of Thessaly in central Greece to the more open cities of Thebes and Orchomenos in Boeotia; participation in the privileged ruling few (*oligoi*) was only a matter of middle-range personal revenue among full citizens. Oligarchic cities such as Croton, Region, Acragas, and Colophon had very large Assemblies (*ecclesiae*) consisting of 1,000 wealthy citizens who legislated by open vote. Sparta had a smaller “executive” body of 30 elders (*gerousia*) advising the hereditary two kings (Glötz 1928; Cartledge 1993).

Athenian direct democracy of the fifth century was an exception that followed well-established formal rules and had two collective bodies of governance: the *Boulé*, a body of 500 citizens selected by draw for a year term from the ten

counties of Attica, met every day, except on holy festivals, to administrate the city. All the citizens (i.e., all 42,000 in 431 BC) had the right to participate in the general assembly (*Ecclesiae*) 10–40 times in a year at the *Pnyx*, a hill opposite to the Acropolis, to decide freely on all the important public matters of the city and to legislate. The farther one lived, the less often he was present to vote. So, distant communes of Attica tended to be underrepresented, this being one of the main problems of Athenian democracy, together with the lack of material motives to participate. Poor citizens would be less willing to participate in the *Ecclesiae*, not affording to lose one day’s wages. After the reforms of Pericles in 460 BC, citizens were paid a small remuneration, little less than a day’s wage for their participation in the Assembly (Glötz 1928; Mossé 1995). But, there were clear advantages as well. Since the voting rule was simple majority by show of hands, it was quite difficult for organized groups to carry the day if they could not convince the majority of the citizens, many of whom changed their minds after hearing the orators’ arguments. There were no formal political parties in the modern sense, but there certainly were political groups representing interests, gathered around some charismatic leaders, such as Cleisthenes, Themistocles, Ephialtes, and Pericles for the democratic “party” and Aristides, Kimon, and Nikias for the aristocratic or rather conservative “party.” The latter was mainly supported by the wealthier landowners and also by medium holders whose revenues came from agriculture, while the farmers and breeders, as well as the traders, artisans, and sailors, supported the democratic side (Finley 1964).

Private and Public Finance and Institutionalized Benevolence

In the great majority of archaic and classical Greek, city-state inhabitants lived mainly of agriculture. Even the rich Athens, Corinth, and Chalkis were mainly inward-looking city-states, but they all had a significant export trade and a commercial fleet as well. Archeological finds in

Italy and Asia Minor prove the flourishing trade of other Greek naval city-states such as Miletus, Ephesus, Colophon, Sybaris, Syracuse, Acragas, and even Massalia (Marseilles). Since the seventh century, golden, silver, and electron coins contributed to the rapid monetization of trade and economic transactions in general. Economic development rapidly changed the life of these naval city-states, while mainland agricultural cities in Boeotia and the Peloponnese declined slowly in power and wealth (Glotz 1928). Individual banks (*trapezes*) appeared early enough to assist commerce with credit and change facilities. Although the institution of the commercial bank appeared only in the Renaissance, ancient capital owners actually acted as bankers lending money with interest to farmers and naval traders (Bitros and Karayiannis 2010). The fact that bankers differentiated interest rates according to the purpose of the loan, offering loans with a nominal rate of 12 % to landowners and up to 30 % to shipowners, proves that they had a clear notion of risk.

Classical Athens had a highly developed system of property rights and duties. Despite property-based distinctions of social rank, inherent to all hierarchical societies, tax burdens and public and military obligations were specified according to each one's income situation. Hence, the city-state of Athens was able to establish an exact contract with its richest citizens in order to ensure the production of both private and public goods and to secure a permanent source of state revenue. The city's public revenues came from rents of public land, custom duties, fines, and war booty. In many Greek cities, rich citizens contributed in a semi-voluntary basis to the public expenditure according to the social institution of *liturgy*. The most important liturgies were the *choregia*, the organization and finance of theatrical productions; the *gymnasiarchia*, the financial support and supervision of athletic training; and the *estiasis*, the organization of public religious feasts (Davies 1981; Gabrielsen 1994; Mossé 1995). Hence, when Athens decided to build 100 ships by means of the silver discovered at Lavrion, to defend the city from the second Persian invasion, an institutional reform introduced a new liturgy, called *trierarchy*. It consisted of

entrusting to the 100 richest citizens the charge of building 100 more new ships so that the Athenian fleet was comprised of 200 triremes, equivalent to the two thirds of the fleet that defeated the Persians in the naval battle of Salamis in 480 BC (Kyriazis and Zouboulakis 2004).

After Salamis, the *trierarchy* system was further developed and refined. Under its new form, the city itself financed the construction of warships but entrusted their maintenance to rich citizens, elected each year. Eligibility was based on the formal rule of property qualification (Glotz 1928; Davies 1981). If an Athenian citizen was able to prove before the Court that there was a richer citizen than himself, then he could avoid the duty. If the supposedly richer man disagreed with the terms, he had to choose to refuse the obligation and exchange properties with the challenger or to undertake the liturgy. This procedure was called *antidosis* (Gabrielsen 1994; Carmichael 1997). A refusal to discharge any liturgy entailed punishment. While the city was safeguarded against fraud by the liturgists by mortgaging their land assets and houses, rich Athenians considered it a duty and an honor to be chosen to finance and manage the production of public goods and services (Lyttkens 1997). To avoid that liturgies do not fall on the same persons for consecutive years, after 378 BC taxpayers were organized in 20 groups called *symmoriae* to share the burden (Mossé 1995).

The Athenian tax system was comprised also of market dues, a tax on sales concluded before state officials, an annual charge of 12 drachmae on *metics* and of 0.5 drachmae on slaves and freedmen, a tax on those who pursued certain callings requiring special supervision (such as oracle mongers, jugglers, and prostitutes), as well as import and export duties. Direct taxation levied on land during the sixth century BC was abolished because it was regarded as an infringement on civil liberty except in times of crises, like the Peloponnesian War, when the Athenians imposed upon themselves a special property war tax *eisphora*. Still, the liturgies functioned as a kind of progressive direct wealth taxation. Redistribution followed indirectly, since the taking over of public goods by the richest citizens liberated

public means to be spent on other purposes, such as a “poor-relief” system, granting assistance to the incapacitated and maintaining the children of those who fell at war, until they came of age.

As it was argued (Ackroyd 1992), lessons from Classical Greece demonstrate that private interests are not incompatible with social justice and public interest insofar as these values are not imposed by a central public power but are enforced by the Law decided by the citizens themselves (ΝΟΜΟΣ ΒΑΣΙΛΕΥΣ).

Greece: Modern Greece 1821–2018, A political History of

Aristides Hatzis

Department of History and Philosophy of Science, National and Kapodistrian University of Athens, Athens, Greece

Definition

Modern Greece has a history of almost two centuries. During these centuries, the country managed to move from the backwaters of Europe to a prosperous liberal democracy before economic crisis hit the country hard in 2010. Greece was founded after a War of Independence from the Ottoman Empire that was based on liberal and democratic principles. This left a political legacy which led to universal male suffrage as early as 1844 and one of the longest parliamentary histories in Europe, despite the tumultuous political life and brief periods of authoritarian regimes. The nineteenth century was a period of a slow modernization of the country (in infrastructure and institutions) but it was also suffocated by “Megali Idea,” the irredentist dream of the enlargement of the Greek state to include all lands, under Ottoman rule, inhabited by large Greek-speaking populations. A great part of Megali Idea was realized in early twentieth century but the triumphs ended with a devastating catastrophe in 1922. Greek political elites were often incompetent and corrupt, but several reformist statesmen managed gradually to achieve convergence with other western European countries. Most importantly, they were very effective in steering Greece on the right (i.e., winning) side of history during every major European or Global conflict (Balkan Wars, World Wars, Cold War). Greece, after World War II and a ferocious Civil War, enjoyed one of the strongest, almost uninterrupted growth on a global level. This led to the accession to the European Communities in 1981 and later the Eurozone. Today, after 10 years of economic crisis and painful austerity,

Greece must meet one of the most difficult challenges: to achieve growth by adopting inclusive institutions.

Greeks in the Ottoman Empire

Greece became an independent state in 1830. Its independence was the result of a national uprising against the Ottoman Empire in the early nineteenth century. After the end of the classical era, Greece was controlled by empires, mostly by the Roman, the Eastern Roman or Byzantine and the Ottoman empires. The Roman and the Byzantine empires were strongly influenced by the ancient Greek civilization and from the seventh century on, Byzantine Empire was linguistically Hellenized.

After the fall of Constantinople, in 1453, the Ottoman Empire recognized the Christian Orthodox Church and the Patriarch of Constantinople as the spiritual but also the political leader of the Greek Christian Orthodox (*Rum*) community. The Christian Orthodox Church, which was dominated by a Greek speaking clergy, was granted several privileges, including some autonomy and judicial jurisdiction in certain private law disputes among Orthodox Christians.

As a result of the power and the great influence of the Ecumenical Patriarchate of Constantinople, at the beginning of the nineteenth century, the Greek Christian Orthodox Commonwealth was so prominent as to capture even high-ranking political stations in the Ottoman administration. Since the late seventeenth century, Greek Christian Orthodox laypeople, “Phanariotes,” who inhabited Phanare, the area around the seat of the Patriarch, had a significant political power. Phanariotes dominated the influential position of Grand Dragoman, the official interpreter for the Imperial Council, but also the position of the Prince (*Voivode*) of the semi-autonomous Danubian Principalities of Moldavia and Wallachia, i.e., modern-day Romania. Phanariotes, many rich merchants, several local communities, and the Church created, from seventeenth century on, a big number of local

but also influential small schools which became, until the nineteenth century, the standard educational units in the Balkan Christian Orthodox communities.

There was also a local Christian Orthodox landed class in Southern Greece, mostly in Peloponnese. The *Kodjabashis* in Turkish or *Proestoi* in Greek were the leaders of their communities. They were part of the Ottoman administration since they were usually responsible for tax collection. These local notables were supported by private armed groups, and they had direct connections to the Ottoman administration and the Patriarchate. They had to deal with dangerous bands of brigands (*klephts*) who had managed to control the mountainous areas of Peloponnese and Central Greece (*Roumeli*) defying Ottoman power and Christian Orthodox notables. In some areas of Central Greece, their power and influence were so significant as to be recruited by the Ottomans as militiamen (*Armatoloi*), supposedly to protect the area from their alter egos, the klephts. Nonetheless, they kept reversing their allegiances according to their interests by alternating between the two roles.

During the eighteenth century, Greek merchants operating in the Balkans and the Asia Minor but also in Central and Northern Europe, including Russia, and Greek shipowners living in small islands of the Aegean and operating in the Mediterranean and the Atlantic, managed to amass great wealth since they controlled a great part of the trade in the Ottoman empire. In the eighteenth and early nineteenth century, they exploited the vacuums in French and English maritime trade during the Second Hundred Years’ War (1714–1815), especially the Napoleonic Wars (1803–1815). One of the consequences of the end in European Wars in 1815 was idle capital and labor in the Greek peninsula, mostly in the islands.

The intellectual elite of the Orthodox Christians who spoke Greek was influenced by the eighteenth century enlightenment, earlier from the other elites in the Ottoman Empire. By the middle of the eighteenth century and in the first half of nineteenth century, major commercial, professional, and academic

(predominantly student) communities of Greek-speaking Orthodox Christians were formed in Vienna, Italian cities, Odessa, and other European metropolitan and commercial centers. Some clergymen and sons of wealthy merchants educated abroad were among the leading proponents of the enlightenment ideas, major works were translated into Greek, and schools teaching Greek were proliferated in key commercial centers. The backlash from the conservative ecclesiastical hierarchy after the French Revolution failed to stop the dissemination of ideas, even in mainland Greece. The half-baked Greek enlightenment undermined the authority of the Church, reconnected the Christian Orthodox elites with Ancient Greece and Western Europe, and created the fertile ground for a revolution that was not only nationalist but also democratic and liberal.

The Greek War of Independence (1821–1832)

The Greek War of Independence was not the first insurgency against the Ottoman Empire in the Balkans. Not even the first by Greek speaking people. The last major uprising by Greeks was the Orlov revolt (1770–1771), incited by Russia's Catherine the Great to distract the Ottomans during the Russo-Turkish War of 1768–1774 and it was rather easily suppressed by the Ottomans.

The French Revolution and the Napoleonic Wars were the events that triggered the Greek Revolution. Rigas Feraios, an intellectual and early revolutionary, tried to secure Napoleon's support for an insurgency in the Balkans but he was betrayed and he was arrested by the Austrians who delivered him to the Ottomans who tortured and executed him. He became the first national hero of modern Greece and he inspired similar revolutionary activities, especially in the Greek diaspora, between merchants, students, and some Phanariotes.

The Greek War of Independence was organized by unlikely revolutionaries: a group of small-time businessmen, with ties to freemasonry and Carbonarism, who founded *Filiki*

Etairia (Society of Friends) as a secret organization, on September 1814 in Odessa. By 1821, Filiki Etairia had hundreds of members in the Greek peninsula, mostly in the Peloponnese, the islands and the Constantinople. The plan was to incite a revolution in the Balkans (from Bucharest to Crete) but the two major points for the break out was first the Danubian Principalities and then the Peloponnese. The leader of the revolution was Prince Alexandros Ypsilantis, a major general of the Russian army and aide-de-camp of Tsar Alexander I.

Still, leading Greek intellectuals, like the liberal Adamantios Korais and statesmen, like Count Ioannis Kapodistrias, foreign minister of Russia from 1816 to 1822, were negative to the idea. They, respectively, believed that Greeks were not ready or that the international situation was extremely hostile to revolutions after the Congress of Vienna (1814–1815).

The Ypsilantis Campaign in Moldavia and Wallachia started on February of 1821 and failed after four excruciating months. Ypsilantis was arrested and imprisoned by the Austrian authorities. He failed to obtain the support of other Balkan peoples, the uprising was renounced by Russia and the revolutionaries were excommunicated by the Patriarchate in Constantinople.

Nonetheless, Greeks took advantage of the fact that Ottomans were distracted by the uprising of Ali Pasha of Ioannina, a powerful warlord who challenged the Ottoman Empire. The suppression of his uprising occupied formidable Ottoman armies for almost a year before and a year after the breakout of the Greek revolution. These forces, thus, were unavailable to quash the insurgents in the Greek peninsula, offering to the revolutionaries the necessary breathing space. Ali Pasha's insurgency was instrumental for the decision by Filiki Etairia leadership to start the revolution during the Spring of 1821.

Even though the Greek revolution was dangerous for the *status quo* that the Congress of Vienna had established in 1815, it generated conflicting sentiments in Europe. Klemens von Metternich, the powerful Chancellor of the Austrian Empire, was very hostile and suspicious

of the Greek rebels. He thought that this was not a purely local insurgency of aggrieved Christians against the cruel and corrupted Ottomans but the sperm of a broader revolution in the Balkans, a threat to multiethnic empires, a radical uprising. He was right. The Greek War of Independence stroke a chord with liberal thinkers and activists but also with romantic poets and writers. These were the Greeks after all, fighting to liberate their “sacred” land from the “uncivilized” Muslim conquerors. The first victories of the Greeks in Peloponnese, Central Greece and the sea (several islands offered a strong makeshift fleet from converted merchant vessels), the Ottoman atrocities against Christian populations (in retaliation for the revolution but also for Greek atrocities) and the intelligent way the revolutionaries presented themselves to Europe had two impressive results: the local insurgency became, almost instantaneously, an international event and scores of influential Europeans, poets (like Lord Byron), and intellectuals (like Jeremy Bentham) decided to support the cause financially or politically. This led to an impressive Philhellenic movement in Europe which was instrumental for the final liberation of Greeks.

The protagonists of the Greek War of Independence came under broad but not necessarily mutually exclusive, categories. Two important groups were:

- (a) The former klephts and *armatoloi* who were brave and shrewd enough to defeat the superior military forces that Ottomans sent to the south. Theodoros Kolokotronis, an ex-klepht, was the most important military leader who also tried to capitalize politically from his well-deserved fame and popularity. However, his view of the world was parochial and his behavior quite opportunistic. He failed to become the “Greek George Washington” because he lacked the American founder’s humility and the political sense to understand what the stakes were.
- (b) The westernized intellectuals, most of them vehicles of liberal and democratic ideas, were the ones who managed to take

over the Revolution. They were former Phanariotes or children of wealthy merchants who studied in Europe and came back to join the Revolution with a clear agenda: to transform the new country into a European constitutional democracy. Their leader was Alexandros Mavrokordatos. They passed, during the Revolution, three liberal and democratic constitutions, approved by national assemblies.

These two factions came to an eventual conflict which was far more multifaceted than a clash between liberals and traditionalists. After the initial military success of the Greeks, there was a ruthless struggle for domination which led to a civil war in two stages. The Ottomans found the opportunity to regroup, asking also the help of Muhammad Ali of Egypt who sent his son Ibrahim to Greece with cavalry and infantry of 20,000 well-trained, by European officers, Egyptian troops. Ibrahim, with the help of other Ottoman forces, managed to quench the revolution in the greatest part of central and southern Greece but his cruel tactics, the massacre of Missolonghi (April 1826) and geopolitical considerations, led to the intervention of three major European powers. The warships of United Kingdom, France, and Russia destroyed Ibrahim’s armada at Navarino bay in October 1827. It took another year for his forces to evacuate Peloponnese, under the pressure of a French expeditionary force. The independence of Greece was declared in February 1830 and with the London Protocol of August 1832, the Kingdom of Greece was established.

Instrumental to this result was the competition among the three Great Powers to influence the direction and the alliances of the new small state but mostly the smart policy of the British foreign minister, George Canning. He was the first to realize that Greece could be a natural and strategic ally in Eastern Mediterranean and the western-oriented Greek faction managed, in 1825, to persuade the revolutionaries to officially ask for the protection of Great Britain. From the mid-1820 (esp. after 1854) to 1947, Greece remained in the orbit of the overbearing British

Empire, being its staunchest ally but also benefiting from the strong political and diplomatic ties with the major power of the era.

Even though the intention of most Revolutionaries, as well as of the Great Powers, was for Greece to become a monarchy, Greeks elected, in 1827, as a President of the new independent state, Ioannis Kapodistrias. Kapodistrias arrived in Greece in early 1828 and realized that the only way to govern over the different factions was with a strong hand. He abolished the Constitution and he assumed dictatorial powers with the initial consent of most representatives in the revolutionary assembly. This was the end of the first Greek republic (1822–1828). However, Kapodistrias was the only Greek who could do the job (statecraft) adequately. His authoritarian reformism, especially his attempt to establish a centralized rule over local notables and warlords, led to his assassination in late September 1831. In less than 4 years, he managed to transform Greece from something resembling a state, with warlords and local notables reigning over poor farmers to a semblance of a European-oriented state. His political agenda was modernization. He organized the administration, he fought highwaymen and pirates, he organized tax authorities and the judiciary, and he tried to secure international loans. His most important legacy was land reform and the establishment of a rudimentary national education system.

Growing Pains: The New Kingdom (1833–1911)

Kapodistrias' assassination is a traumatic event in Greek history. His death led to 16 months of civil unrest and anarchy. So, when the Great Powers elected the Bavarian Prince Otto from the House of Wittelsbach for the throne of the new Kingdom in 1832, almost everyone in Greece received their decision with a relief. The 17-year-old Otto arrived in Greece in early 1833 with a Regency council who governed Greece for almost 3 years, until Otto reached majority. Both the Regency Council and Otto were autocrats. Despite the popularity of the young King, his

absolutism and the fact that he was a Roman Catholic, married to the Protestant and childless Amalia, were among the causes of resentment together with austerity measures he had to adopt, including suspension of benefits to war veterans, due to Greece's insolvency. This led to a bloodless insurgency on September 1843. The uprising was supported by the military garrison of Athens and several politicians. Otto had to yield to their demands. He promised to grant a constitution and to terminate the involvement of Bavarians in the administration. The new Constitution was proclaimed in March 1844, transforming Greece into a constitutional monarchy with a bicameral parliament. With the electoral law of March 18, 1844, Greece was the first country in the world to introduce universal male suffrage – nine out of ten male adult citizens obtained voting rights. However, Otto's destabilizing constitutional transgressions and his direct involvement in politics led to more bitterness and criticism. In October 1862, he was forced to abdicate and leave Greece.

The Bavarian legacy is mixed. The three decades were a period of establishing hierarchy and bureaucracy in the public administration and the army, of organizing education and judiciary, of modernization and Europeanization. One of the regents, the law professor Georg Ludwig von Maurer, was instrumental in the process of the adoption of modern European institutions and legal codes by the new state but also of the unpopular "nationalization" of the Greek Orthodox Church, even though he stayed in office for only 18 months. Otto had moved the capital from Nafplion to Athens for obvious symbolic reasons. During his reign, he adopted the irredentist policy of the "Great Idea" (*Megali Idea*), i.e., the enlargement of the Greek state to include all lands under Ottoman rule inhabited by large Greek-speaking populations, including Constantinople, southern Balkans, the Aegean Sea islands, Crete, Cyprus, and the western part of Asia Minor. From 1844 to 1922, irredentist nationalism became the dominant policy for Greece leading to impressive territorial expansions but also to a major catastrophe. One of Otto's major failures was to take advantage of

the Crimean War (1853–1856) in order to expand against the Ottoman Empire.

Otto's abdication was the result of an uprising against his reign. His successor was a Danish Prince from the House of Glücksburg who became King George I and reigned for half a century, from 1863 to 1913. He was a solid anglophile and willing to accept a democratic constitution. With the new constitution of 1864, Greece became one of the first parliamentary democracies in the world, especially when the democratic principle was reinforced in 1875 when popular sovereignty was guaranteed by the introduction of the constitutional principle that the government should enjoy the confidence of the Parliament.

The leading reformist political leader of the late nineteenth century was the liberal Charilaos Trikoupis. From 1875 to 1895, he dominated Greek politics. He became prime minister seven times and he governed more than a decade in total. He began his career fighting the constitutional transgressions of King George I. During his tenures, the infrastructure which modernized Greece was built, but it was funded by foreign loans, leading the country to bankruptcy in 1893. A few years later, in the summer of 1896, Athens hosted the first international Olympic Games in modern history but Greece had also to face an "unfortunate" war with Turkey in 1897.

From 1864 to 1881, Greek territory was enlarged peacefully. Britain ceded the Ionian islands to Greece in 1864 as a gift and rewarded Greece with Thessaly and part of Epirus, for not siding with Russia, despite the nationalistic temptation, in the Russo-Turkish War of 1877–1878. However, these minor territorial gains couldn't satisfy Megali Idea, in an era where the Eastern Question preoccupied the minds of governments and people in the Balkans. The evolving Cretan question (Cretans revolted almost uninterruptedly against the Ottoman authorities during the nineteenth century) pressured enormously the Greek governments and kindled nationalistic feelings. Nevertheless, British protection again ensured that Greek territory remained intact, even after the Greco-Turkish War of 1897 while Crete became autonomous in 1898 under Prince

George of Greece. But Greece's military defeat led to a national humiliation and the imposition of international control of Greek finances which led to an impressive fiscal consolidation.

Belle Époque was not so superb for Greece. The bitter military defeat and the bankruptcy led to the disillusionment of Greeks and resentment against the Palace. The Cretan issue was not considered resolved since Cretans themselves were not satisfied with autonomy, they wanted to be united with the "motherland." At the same time, a new antagonism begun in Ottoman Macedonia, mostly between Greeks and Bulgarians. From 1893 to 1908 (when the Young Turks Revolution took place), the two countries used armed propaganda, cultural and religious influence to attract and subdue the mixed-ethnically people living in Macedonia. Additional chronic problems, during the nineteenth century, were political corruption, rigged elections, a powerful clientelist system, and a dysfunctional bureaucracy.

The turmoil in Macedonia but mostly in Crete and the initial success of the Young Turks led to the first military coup in the twentieth century Greece. The pronunciamiento was bloodless, organized by young and politically inexperienced military officers without a clear political agenda, in mid-August 1909. The government capitulated to their demands, but a political stalemate was the inevitable outcome of their indecisiveness. Finally, they offered the political leadership to Eleftherios Venizelos, a middle-aged Cretan politician and former revolutionary. Venizelos arrived in Greece and decided, reluctantly at first, to play the political game by levelling first the play field. He was a political genius and the greatest statesman in modern Greek history. He dominated Greek politics for 25 years with his impressive successes but also failures and his polarizing figure. From 1910 to 1915, he managed to gain the trust of King George I, he was appointed Prime Minister, he won election after election, he founded the first modern Greek political party (the Liberal Party), he amended the constitution (in 1911), he enforced many structural reforms in almost every area: from the reorganization and training of the army to education.

The Decade of Triumph and Tragedy (1912–1922)

The disappointment that followed the promise of the Young Turks Revolution for equality and democratic representation of the minorities and the ripening of the Eastern Question were two of the reasons behind the Balkan Wars of 1912–1913. A military alliance of Bulgaria, Serbia, Montenegro, and Greece attacked the Ottoman Empire in October 1912. Bulgarians and Serbians, with their strong armies, never believed that the relatively weak Greek army would be so successful and fast as to reach the finishing line first by capturing Thessaloniki, the bone of contention between the Balkan allies. Bulgaria was so disillusioned by the unforeseen Greek success as to attack Greece and Serbia after the first stage of the Balkan Wars. The Greek army was able to defeat the strong Bulgarian army and gain some additional territory. The greatest part (51%) of the apple of discord, Macedonia, became a part of the Greek state. This was the result of Venizelos' political and diplomatic genius. But he shared the credit with Prince Constantine, the son and heir of King George I who was also the military commander in chief. Venizelos and Constantine's relationship at the end of the Balkan wars was overcast by their disagreement as to the strategic objectives of the Greek expansion. King George managed to control his insolent son and to satisfy his successful prime minister, minimizing the cost of their divergence. He moved temporarily to Thessaloniki to symbolize the accession of the new territory to Greece. A few months before his golden jubilee in 1913, he was assassinated by a drunkard with anarchist sympathies. The box of Pandora was now open, as his son, became King Constantine I.

Greece had managed to double its territory and population by acquiring southern Macedonia, southern Epirus, most Aegean islands, and Crete. The integration of these new territories with sizable ethnic and religious minorities and the efficient administration was not an easy task for the small Kingdom. Nevertheless, for almost a century, Greeks waited impatiently for the Megali Idea to be realized and now, after all these years and many disappointments, everything signified that they

were on a roll. They saw Venizelos as the one who made it happen politically, but Constantine was also extremely popular as a successful military leader and a symbol: he was the first King born in Greece and raised as a Greek-Orthodox, the one destined to restore Greece to greatness.

The confrontation between the two seems inevitable with hindsight. They both were strong-minded, but their views differed. Venizelos was a liberal, a staunch anglophile and he represented the interests of the most dynamic part of the new bourgeoisie. Constantine was a believer in the divine rights of monarchy, with populist impulses and rather unrelenting in his prejudices. But worst of all, Constantine was strongly pro-German. When the first World War I broke out, their conflict evolved into a National Schism, a traumatic experience with devastating consequences. From 1915 to 1936, Greece was bitterly divided between anti-Venizelists and Venizelists and eventually (after 1924) to royalists and republicans.

It was a conflict of foreign policy. But it was also a constitutional crisis. Venizelos insisted that Greece should enter the Great War on the side of Entente but Constantine was adamantly against, he favored neutrality but he also schemed in the back rooms for the benefit of the Central Powers. Venizelos resigned but even though he triumphed at the national elections, Constantine didn't relent. He saw foreign policy as his royal prerogative. Venizelos resigned for the second time. Entente pressured ruthlessly the royal governments that followed to submit to its demands and, when German-escorted Bulgarian troops seized part of the Greek Macedonia, Venizelos decided to set up a provisional government in Thessaloniki with the support of the French army. Greece was torn. There was even an armed confrontation in the streets of Athens between the army of the royalist government and French forces in November 1916, which led to an even deeper wedge between royalists and Venizelists. A naval blockade by the Allies made Constantine leave Athens (he didn't abdicate) together with his first-born son and heir, George, in June 1917. Venizelos returned to Athens and assumed power. Alexander, the second-born son of Constantine, became a kind of "interim" King. He was ideal for the job. A malleable individual, he was easily handled by

Venizelos. Greece entered the war on the side of the Allies at the last stage of it helping them in their offensive in May 1918 that led to the capitulation of Bulgaria.

The fact that Bulgaria but also the Ottoman Empire sided with the Central Powers who lost the war gave Greece an enormous diplomatic advantage. Venizelos reinforced this advantage by sending Greek troops, in 1919, to fight the Red Army together with the White Forces at the multinational military expedition in Ukraine. Venizelos proved himself the most credible ally in the Balkans and he was splendidly rewarded in the Treaty of Sèvres of 1920. Western and Eastern Thrace were delivered to Greece. The Greek army reached the outskirts of Constantinople and landed in western Asia Minor, Smyrna (today Izmir) and a large surrounding area with the objective to annex it to Greece, with the approval of the Allies, after a referendum.

Venizelos could not enjoy his well-deserved triumph. King Alexander died unexpectedly and himself was nearly killed in an assassination attempt by two royalist officers. The elections his government held in November of 1920 to capitalize politically on his successes led to a defeat. A disheartened Venizelos left Greece for France. The exultant royalists organized a plebiscite to bring back Constantine, despite stern warnings by the Allies.

An ailing and less confident Constantine and his incompetent governments ruled Greece for the next 2 years taking revenge against the Venizelists and trying to cajole the British. Their foolish blunder was a futile attempt to destroy the Turkish forces led by Mustafa Kemal (later Atatürk) by reaching and capturing Ankara. This was a strategic mistake comparable to the French and German invasion of Russia in the nineteenth and twentieth century. After 2 years of pyrrhic victories, the Greek army was defeated and retreated, leaving Smyrna to the advancing Turkish army. Smyrna was destroyed, and its Greek inhabitants were killed, captured, fled, or deported. The, more than 2,500 years, Greek presence in Asia Minor ended with the greatest catastrophe in Modern Greek history. It was also the end of Megali Idea. Greece had to abandon eastern Thrace, Smyrna, and two small Aegean

islands. Greeks left their ancestral homelands in Pontus and Cappadocia.

Bitter Divide: The Interwar Period (1922–1940)

After the catastrophe, a military coup, organized by mostly Venizelist officers, made Constantine abdicate in favor of his firstborn son who became King George II, but only temporarily. The process of transforming Greece into a republic had started. The radical Venizelist officers organized a mock martial court trial of the leadership of the royalists. Six of them were sentenced to death and they were speedily executed. Their execution led to political scars that for several decades plagued Greece. The royalists abstained in the 1923 national elections and the result was the political dominance of republican liberals for the next decade. On March 25, 1924, the second Greek Republic was proclaimed and a new constitution was adopted in 1927, but most royalists didn't accept the new regime and the National Schism deepened. To make matters worse, one radical republican, General Theodoros Pangalos, assumed dictatorial powers for a year. One of the challenges was to accommodate 1.3 million refugees from Asia Minor who integrated themselves completely only after decades.

Venizelos returned to power after a landslide electoral victory in 1928. His tenure from 1928 to 1932 was one of the most fruitful in almost all areas. From structural and institutional reforms to international relations. Even though the refugees were a great part of his electorate, he dared to visit Ankara and sign a friendship agreement with Atatürk, ending a century of conflict. However, the Great Depression led Greece to economic destabilization and to the loss of majority support to Venizelists. The anti-Venizelists ("People's Party") came back to power with a vengeance in the 1933 elections, ending the dominance of the Liberal Party and eventually capturing the bureaucracy and the military. Venizelos (dismayed after a second attempt against his life) and the republican officers tried to prevent the restoration of the King with an ill-executed coup in 1935 which led Venizelos to an

exile in Paris where he died the following year. George II returned with a rigged plebiscite. This was the end of the second Greek Republic (1924–1935). The Liberals accepted the regime change, but it was not enough. The rise of the Greek Communist Party and a wave of labor strikes was used as pretext by George II to accept a dictatorship under Ioannis Metaxas, an experienced and competent but ruthless retired officer and royalist politician. The Greek people tired by almost three decades of wars and political turmoil didn't resist to the new regime which was developed into a conservative authoritarian government fashioned after Fascist Italy.

The Decade of Wars (1940–1949)

Despite the rise of Nazi Germany, George II and Metaxas had learned their lesson from World War I. They had decided to keep Greece neutral, if possible, but if there was no choice, to remain faithful to Britain. When Mussolini, in October 1940, invaded Greece, the King and Metaxas decided to fight back, the Greek people totally agreeing with their decision and fighting bravely. The Greek army not only fended Italian forces off but also it managed to humiliate Mussolini by advancing in the under Italian control Albania capturing one city after another. This was the first military success against the Axis, so Hitler had to intervene while he prepared Operation Barbarossa against the Soviet Union. Germans invaded Greece in April 1941. The exhausted Greek army and a small British expeditionary force was not able to protect the country. Nevertheless, it took Germans almost 2 months to occupy the whole of Greece due to the fierce resistance by Greek and British forces in Crete.

King George (Metaxas died unexpectedly in early 1941) fled to Egypt where he appointed a new prime minister, the former Venizelist, Ioannis Tsouderos. In Athens, a puppet regime was established by collaborationists. Greece was separated in three different zones, occupied respectively by German, Italian and Bulgarian forces. Several resistance groups were established from the very beginning in mountainous areas with the

help of the British. The most well organized was EAM, that was controlled by the Communist Party with the same agenda as similar partisan organizations in occupied Eastern Europe, i.e., to distract German forces in their invasion of Soviet Union and to seize power after the end of the war.

EAM and its military branch, ELAS, managed to annihilate almost every rival resistance group and dominate the field. When the defeat of Germany was more than obvious, the puppet regime tried to organize paramilitary groups to prevent the capture of power by the communists after the German retreat. EAM formed a provisional government in order to impose its participation to the government in exile. A compromise was achieved with the backing of the British and a coalition government was formed under a seasoned liberal politician and a former associate of Venizelos, George Papandreou. Papandreou returned to Athens after the departure of German forces in October 1944 but EAM/ELAS controlled the rest of the country. The communists could have grabbed power rather easily. However, Winston Churchill had already secured Greece for the West in his negotiation with Stalin and the latter didn't encourage Greek communists who were baffled. The behavior of EAM ministers in the coalition government was not cooperative and the noncommunist members didn't trust them. EAM didn't want to disarm its army and relinquish the control of the periphery.

After the bitter resignation of its ministers, EAM organized a strong demonstration in early December 1944. The demonstration had a wretched ending after police killed several demonstrators. This led to a bloody confrontation in the streets of Athens: The numerically superior EAM/ELAS tried to seize control of the capital against the British forces stationed in Athens which were supported by a coalition faithful to the government: veterans from the Greco-Italian war and the North Africa Campaign, right-wing guerilla groups, policemen, even some former collaborationists. The communist forces were far superior, but they couldn't defeat this unlikely pro-government coalition. Winston Churchill ordered troops from the Italian front to join the small contingent in Athens and quell the

rebellion. Under considerable domestic pressure, the British prime minister deemed the situation critical enough for him to spend Christmas day in Athens, in an inconclusive mediation effort. Overpowered, the communists capitulated and accepted the disarmament of ELAS.

However, atrocities from both sides (Red/White terror), the decision of the Communist Party to abstain from the first postwar national elections in March 1946 (leading to a triumph for the royalist Right) and the return of King George II after a referendum polarized even more the Greeks and led to the final stage of the Civil War (1946–1949). This time the Communist Party had decided to fight to the end. The prospects were good: the communists controlled many parts of Greece, the kindred governments of Albania, Yugoslavia, and Bulgaria already provided material support and safe haven for the communist army, Soviet aid was anticipated while the exhausted British Empire relinquished its traditional role in Greece. But, it was replaced immediately by the United States who decided to assert its role as the postwar superpower, providing abundant economic and military support to the Greek government, under a veteran leader of the minority Liberals, Themistoklis Sofoulis. The failure of the communists to capture and hold any significant town was exacerbated by the Tito-Stalin split which eventually led to Yugoslavia closing its borders. After two inconclusive years of fighting, in summer 1949, the government forces launched their final assault against the communist stronghold on the mountains of northwestern Greece. By the end of August, the remnants of the defeated communist forces fled to Albania.

From Illiberal Democracy to Dictatorship (1949–1974)

Greece remained part of the western democratic world (joining NATO in 1952), but the price was an illiberal (tutinary) democracy which treated the defeated communists (and fellow travelers in general) harshly, deepening the rift instead of investing in reconciliation. The United States

exerted an enormous influence on Greek politics while the King (Paul, the third son of Constantine I succeeded George II in 1947 and Paul's son Constantine II succeeded his father in 1964) antagonized elected governments, especially during the mid-1960s. Nevertheless, Greece remained a democracy. The Communist Party was banned but it was represented by a leftist party, a political front, which, 9 years after the end of the Civil War, managed to become, for a brief period, the second strongest party in parliament. The leading politician of the period was Konstantinos Karamanlis, a conservative reformist who in 8 years (1955–1963) transformed Greece. He successfully pursued Greece's association with the European Communities and he was responsible for the most spectacular economic growth due to rapid industrialization and investment in infrastructure and tourism. Karamanlis also managed to reach a compromise solution for the Cyprus problem which since the early 1950s had plagued Greece's foreign relations and domestic politics. Greek Cypriots were the majority (78%) in the, under British administration, island. Nonetheless, there was a sizable Turkish Cypriot minority (18%) who felt threatened by the prospect of *Enosis* (the union of the island with Greece). Rather than insisting on *Enosis*, Greece agreed with Turkey and Great Britain for Cyprus to become an independent Republic in 1960. After a quarrel with King Paul, Karamanlis resigned and then lost the elections of 1963 to a centrist party led by George Papandreou. Papandreou himself had to resign in the summer of 1965 when the young King Constantine denied him his constitutional prerogative to discharge the defense minister of his government.

A period of political turmoil led to a military coup, organized by colonels against the political system in general in April 1967. Constantine II fled the country 8 months later, after a failed counter-coup, and all political activity ceased for 7 years. The self-confident leader of the military junta, George Papadopoulos, proclaimed Greece a "republic" in 1973, appointed a docile civilian government, and announced (controlled) elections for the following year. His plans went awry after student riots in November 1973 gave to the

regime hardliners an excuse to sack Papadopoulos and forestall the supposed liberalization process. Their foolish mistake was the attempt to assassinate the President of the Republic of Cyprus, Makarios, in order to annex Cyprus to Greece in mid-July of 1974. Turkey invaded Cyprus (the north of the island is still occupied by Turkish forces) and the chain of events led to the fall of the humiliated military junta. Konstantinos Karamanlis returned on July 24, 1974, to Greece after a self-imposed exile of 11 years.

The Third Greek Republic: From Metapolitefsi to the Economic Crisis (1974–)

Karamanlis, as the prime minister in a coalition government, managed to restore democracy (*metapolitefsi*) in a paradigmatic way, he legalized the Communist Party, and he passed several necessary structural reforms. Greece became a Republic with the constitution of 1975 (currently in force) after the 1974 referendum which ended Greek monarchy. It was the beginning of the current period of the Third Greek Republic which is the less tumultuous in modern Greek history. Karamanlis governed from 1974 to 1980 when he was elected President of the Republic. In January 1981, Greece became a full member of the European Communities.

The 1980s were dominated by the socialist party PASOK under its charismatic leader Andreas Papandreou (son of George) whose welfare populism triumphed. He governed Greece from 1981 to 1996 with a short interval (1989–1993) when the conservative party of Karamanlis (New Democracy) returned to power with a liberal reformist leader, Constantine Mitsotakis. PASOK's dominance continued after the death of Papandreou with the reformist social democrat, Kostas Simitis, as prime minister. Simitis' 8-years tenure was marked by high growth rates and Greece's accession to the Eurozone but with no major structural reforms. He was succeeded by Kostas Karamanlis (the nephew of the former Prime Minister and President) whose free-spending policies precipitated the Greek debt crisis of 2009–2010.

Karamanlis lost the 2009 elections to PASOK's George Papandreou (son of Andreas) who had to deal with the sovereign debt crisis. In May 2010, Greece entered a bailout agreement with the Eurozone countries and the IMF. Two more bailouts followed since, reaching loans to Greece to a total of over €250 billion. The adopted austerity measures agreed between Greece and its creditors (three economic adjustment programs) led to a remarkable fiscal consolidation but they stagnated the economy. This was so, because mostly fiscal measures were adopted and only some half-baked institutional reforms were enforced. The first bailout agreements were enforced by PASOK and then two coalition governments formed by New Democracy and PASOK. At the end of 2014, Greece was in a process of fragile recuperation which was upset by the victory of the radical leftist and populist SYRIZA. SYRIZA tried to renegotiate the bailout agreement by following a self-defeating brinkmanship strategy which led to its bitter capitulation in July 2015. The third bailout agreement included austerity measures, harsher than the preceding ones. Since then SYRIZA and its leader Alexis Tsipras managed to secure their power by cooperating with the creditors in a government coalition with a minor ultra-right-wing party. Despite its obvious failure to deliver on its electoral promises to get rid of austerity, this coalition outlived all preceding bailout governments.

Greece in the Twenty-First Century

Modern Greece has a history of almost two centuries. During these centuries, the country managed to move from the backwaters of Europe to a prosperous liberal democracy. From 1929 to 1980, Greece had an average annual rate of growth of income per capita of 5.2% (during the same period, Japan had an average of 4.9% and Germany 3.0%). However, this development was based on extractive institutions. The membership in the European Union and the Eurozone helped Greece put its extractive institutions under the rug of EU convergence funds, cheap international borrowing and fudged statistics. The crisis of

2008 was the triggering effect of the perfect storm that hit Greece in early 2010. Greece must replace its extractive institutions with inclusive institutions suitable for economic growth. This should be the new “Megali Idea” for the Greek people.

Hard Law

Katarina Zajc

Laws School, University of Ljubljana, Ljubljana, Slovenia

Abstract

Hard law represents rules that are binding and precise and delegate the power either to explain or adjudicate to third parties. Soft law, on the other hand, does not have a status of a binding rule but nonetheless influences the behavior of public. The literature still debates whether the hard and soft law are either complementary or antagonistic. Especially with development of EU, we can see that soft law has gained momentum. We will see more soft law in the areas of uncertainty or in areas where the changes are day-to-day occurrence or where soft law usually paves the way for the hard law.

Definition

Hard law refers to legally binding obligations that are precise (or can be made precise through adjudication or the issuance of detailed regulations) and that delegate authority for interpreting and implementing the law. (Abbot and Snidal 2000)

Soft law, on the other hand: "... consists of rules issued by lawmaking bodies that do not comply with procedural formalities necessary to give the rules

legal status yet nonetheless influence the behavior of other lawmaking bodies and of the public." (Gersen and Posner 2008)

The desire to gain and distribute rights among people and the disputes about rights are as old as human race. Therefore, usually governments/states take on the role of enacting the rules in order to distribute the rights and solving disputes. Even though Coase (1960) claimed that rules are not necessary if the rights are distributed and transaction costs are zero. However, we do not live in the world of zero transaction costs, and rules might be therefore beneficial.

Broadly speaking, the governments/states have either hard law or soft law at their disposal, depending on the goal that they try to reach with enactment of the rules and the advantages and disadvantages associated with each.

Even though definitions of hard law vary to a certain degree, the literature agrees that hard law represents rules that are binding and precise and delegate the power either to explain or adjudicate to third parties (Abbot et al. 2000). Hard law rules therefore have to be precise in such a way that it is unambiguous what kind of conduct they prescribe or require even though some hard law rules are and can be somehow relaxed along its dimension. If they are too relaxed, they might fall under the realm of soft law, even though they are binding and delegate the power to adjudicate to some third party. Hard law puts obligations on the entities within the realm of the jurisdiction of the hard law,

and if the entities breach their obligations, the sanctions are prescribed *ex ante*. For example, almost all legal regimes include a maxim “*neminem laedere*,” the obligation of not hurting anybody. If somebody commits a tort and is found liable in the court of law, it usually has to pay damages, which range is prescribed in law *ex ante*. Committing a crime usually means times in prison, which is also predetermined in hard law *ex ante*. Delegation means that special institutions, for example, courts, arbitrations, and similar bodies, have the authority to interpret the legal rules to a certain degree and to adjudicate the dispute.

Hard law is enacted in the parliamentary bodies of countries, and very rigorous rules are used in order to pass the hard law in the parliament. Usually, the rudimentary rules about the enactment of hard law are legislated in the Constitution and further elaborated in certain legislative acts. For example, in a parliamentary system with bicameralism, only the government, each parliament member, a higher parliamentary chamber as a whole, or a certain number of voters can propose an act. (Article I, section 7 of the US Constitution requires that a bill be approved by both houses of Congress and signed by the President.) The proposal of an act has to have certain elements, for example, the reasons for enactment of the act, goals of the enactment, financial consequences for the country’s budget, confirmation that there are enough assets in the budget to support the act once, and if, enacted, comparative study. There are usually certain prescribed phases through which the act should go before the final vote is taken in one of the chambers of the parliament. Once the lower chamber passes the law (using different majorities as prescribed either by the Constitution or other acts), the higher chamber has to pass it too. They can veto the act and then the lower chamber has to pass the law with higher majority than the first time, for example, with absolute instead of the relative majority. The president usually executes the act and the act is published in the official gazette.

Advantages and Disadvantages of Using Hard Law as Opposed to the Soft Law

One of the main advantages of hard law is that it reduces the transaction costs of subsequent transactions, since the rules, once enacted, regulate all future behavior regulated by the act. (see Abbot and Snidal 2000.) For example, if the parties are in a contracting relationship, they do not have to either negotiate over the provisions (even though not all provisions are defaults in a sense that the parties can contract around, one of the provisions are mandatory, meaning that the parties cannot change them with the contract) or do not negotiate at all about the provision enacted in the Law on Obligation. The transaction costs of contracting are therefore decreased. Also, hard law, in domestic law and in international relations, strengthens the credibility of commitments and decreases the costs associated with the problems of incomplete contracts. Parties of the contract, for example, know that if one of the parties breaches the contract or obligation, they could file a claim at predetermined institutions which must adjudicate according to rules and impose sanctions determined by law and can therefore rely on the promises made by the parties in the contract. In other words, adjudication is guaranteed and costs of it are fixed and determined *ex ante*. Credible commitments are crucial in situations when one party performs its obligations before the other party, when there are asset-specific investments made upfront, basically in any situation in which one party is vulnerable to the other. Without such credible commitments, the number of transactions would drop or transactions would be made among parties that know and trust each other, which diminished the number of potential partners and consequently the advantages of contracting.

Disadvantages of Hard Law

A major disadvantage of hard law is the cost of its enactment. As already described, the procedures

are rigorous, and the agreement among the parties deciding about enactment of the hard law must be pretty high. Also, once the act is passed and in the case that is very precise, it cannot adjust to the changed circumstances which might not be advantageous in certain circumstances, for example, in the area of finance where changes are occurring daily. However, it should also be pointed out that even some procedures to enact soft law can be very costly.

Interaction of Hard and Soft Law

The literature still debates whether the hard and soft law are either complementary or antagonistic (see Shaffer and Pollack 2010.) Complementarity is seen in two ways. Soft law can lead to adoption of hard law with the same content, and hard law can be further elaborated and explained through soft law provisions. However, especially in the international relationships, the hard and soft law can be antagonistic, especially in the situations of significant distributive conflicts and pluralistic regime complexes. The antagonistic interaction of hard and soft law can in the mentioned situations lead to “hardening” of the soft law and “softening” of the hard law.

Conclusion

Hard law might be advantageous to reach some goals of the government. However, especially with the development of the EU (Trubeck et al. 2006), we can see that soft law gained momentum. As literature claims, we will see more soft law when the formalities of the hard law rise relative to the costs of the soft law. It could be also said that we will see more soft law in the areas of uncertainty or in areas where the changes are day-to-day occurrence as, for example, on the financial markets where rules should be very flexible. Also, as we see predominantly in the EU law, soft law usually paves the way or tests the waters for the hard law.

Harmonization of Tort Law in Europe

Mauro Bussani^{1,2} and Marta Infantino¹

¹University of Trieste, Trieste, Italy

²University of Macau, S.A.R. of the P.R.C., Macau, China

Abstract

The aim of the entry is to provide an overview of the projects regarding harmonization of European tort laws and the costs and benefits associated with them. To this purpose, the entry critically examines the arguments for and against tort law harmonization in Europe and investigates the assumptions and approaches underlying the many institutional and academic initiatives in the field. The entry tentatively draws some conclusions about the short- and long-term prospects of European tort law harmonization.

Definition

Processes aiming to align European tort law rules and practices, either through hard or soft law measures.

Introduction

In the past decades, the idea of harmonizing European private laws has been high on many agendas – especially in the EU institutions and among European legal scholars. While at the beginning institutional and doctrinal efforts mostly focused on contract law, tort law has recently been added to the picture, and its harmonization at the European level has now become a primary goal for many EU institutions and research groups.

The aim of this entry is to offer an overview of the various projects regarding harmonization of European tort laws and the costs and benefits associated with them. To this purpose, the entry will start with a description of what European tort laws have and do not have in common (section “[The Variety of European Tort Laws](#)”). Against this framework, we will be able to appreciate the arguments that have been put forward for and against tort law harmonization in Europe (section “[Harmonization’s Pros and Cons](#)”), as well as the assumptions and approaches underlying the many institutional and academic initiatives in the field (section “[The EU’s Piecemeal Approach](#)” and “[Scholarly Endeavors](#)”). We will first deal with the steps taken by the EU institutions in harmonizing substantive and conflicts of law rules in tort law matters (section “[The EU’s Piecemeal Approach](#)”). We will then investigate the main features of the research groups that have recently been established to support – although through different means – the Europeanization path (section “[Scholarly Endeavors](#)”). Some of these initiatives, like the *European Group on Tort Law* and the *Study Group on a European Civil Code*, seek to draft a “soft” European tort law, e.g., a law the binding force of which is not derived from the official authority conferred by its source but from the high reputation enjoyed or

displayed by its compilers (section “[Striving for Harmonization: The European Group on Tort Law and the Study Group on a European Civil Code](#)”). Other projects refuse to devise solutions and engage instead in deepening the dialogue between European legal cultures. This is particularly the case with two projects – the *Ius Commune Casebook for a Common Law of Europe* and the *Common Core of European Private Law*. Despite some divergence, both are devoted to developing a better knowledge of European legal landscapes (section “[Building Knowledge: The Ius Commune Casebooks for the Common Law of Europe and the Common Core of European Private Law Project](#)”). Such an overview will allow us to draw some conclusions about the short- and long-term prospects of European tort law harmonization (section “[Conclusions](#)”).

The Variety of European Tort Laws

European tort laws are far from being harmonized. Judicial opinions in tort disputes (as in any private law conflict) range from being concise and, in principle, self-contained, such as the French Cour de Cassation’s rulings, to being lengthy and full of references to academic literature as is the case in Germany (Quézel-Ambrunaz 2012, 108; Markesinis and Unberath 2002, pp. 9–12). They may look like unanimous and anonymous decisions of the court (civil law), or, as in common law, they may show the individualized opinion of individual judges, be they concurring or dissenting (van Dam 2013, pp. 53–5, 75–7, 95–7). Legal scholarship plays a role in (tort) law-making processes which is strong and evident throughout the continent except England (Bussani 2007a, p. 378). In continental Europe, tort law reasoning usually starts with the black-letter words that legislators use in codes and statutes, while in common law countries the same role is played by judicial doctrines hardened into precedents (Bussani and Palmer 2003, pp. 120–159).

Fault-based rules are presented everywhere as the foundation of the tort law system (Werro and Palmer 2004, p. 13), but they may either be open ended, attaching liability for any conduct which

causes damage to another (e.g., France, Italy, Poland), or may provide for liability only in certain situations, thereby restricting recovery to the breach of specific duties (typically England) or to the infringement/violation of a list of specific interests (such as Germany, Austria, Scandinavian countries) (von Bar 2009, pp. 229–33). General rules on fault liability may require the plaintiff to prove the defendant's negligence (Western Europe) or may state that once the damage is proved, the defendant's negligence is presumed (post-socialist countries) (Menyhárd 2009, pp. 350–2). Resort to strict liability rules may be made routinely (as in France) or as an exception (as is the case in England), with a range of intermediate positions (Werro and Palmer 2004, pp. 29–31). Vicarious liability for acts of a minor or an employee, which in German tort law is grounded in the responsible person's fault in supervision, is in the majority of the other jurisdictions imputed to him/her in an objective manner (Werro and Palmer 2004, pp. 393–6). Different from other European legal systems, in France (and to a certain extent in Belgium), the plaintiff is barred from suing the defendant(s) in tort if there is a contract between them (although the plaintiff can combine, in a single proceeding, actions in contract and in tort against different defendants) (Giliker 2010, p. 44; von Bar and Drobnig 2004, pp. 198–9). In Scandinavian countries, the impact of insurance on tort law mechanisms is more pervasive than anywhere else, effectively turning tort law into a residual remedy in many areas (Palmer and Bussani 2008, pp. 65–6; Bussani and Palmer 2003, pp. 156–8; Ussing 1952). Punitive damages and jury trials are available in England in an extremely limited number of cases but are almost unknown throughout the continent (Magnus 2010, pp. 106–7). European systems also diverge as to the (limited) extent to which they allow the procedural aggregation of victims' claims and contingency fee agreements between lawyers and their clients (see, respectively, Oliphant 2010, pp. 120–124, 163–164, 204–209, 287–288; Reimann 2012, pp. 3, 45).

Similarities and differences of course do not end there, but these illustrations suffice to make

clear the great variety of European tort laws. It is a variety that at first sight – but at first sight only – may resemble the scenario in the United States, where increasing divergence between the federal and states' (tort) laws pushed the *American Law Institute* to launch, in the late 1920s of the twentieth century, the idea of the *Restatements of the Law*. Such a first impression presented by the analogy would, however, be wrong. There are considerable differences between the European case and that of the United States. We will not point out how punitive damages, jury trials, aggregation of claims, and contingency fee agreements are largely unknown to European tort laws, while they shape the basic vocabulary of tort law in the United States (Magnus 2010, pp. 102–24). There is more to it than this. Although the United States display 51 tort law jurisdictions, including the federal one, these regimes largely share a common language and employ the same reservoir of notions and technicalities. Most US legislatures are affected by the same pressures coming from power groups acting across state boundaries, like the insurance industry and the American Trial Lawyers Association. Moreover, the US Supreme Court, in matters it can intervene in, operates as a driving force for uniform outcomes (Palmer and Bussani 2008, pp. 52–3; Stapleton 2007, p. 25). Europe, by contrast, lacks one Supreme Court for private law matters. The insurance market is still not homogeneous, and lawyers are associated at the national level only. There is no common language, but 24 distinct ones, and every legal system relies upon its own set of notions and technicalities – a set that, as we just saw, may significantly overlap but may also greatly diverge among different jurisdictions.

Harmonization's Pros and Cons

As said above, the idea of harmonizing the variety of European tort laws for a long time did not attract the attention of institutions and scholars. Up until the 2000s it was monopolized by promoting legal convergence of contract laws, thought as the area that impacted business activities directly (Bussani 2007c; for the observation

that convergence would be easier in contract law rather than in tort law, insofar as contract laws are all inspired by the aim of facilitating trade, while tort laws are closely linked to domestic preferences as to what is to be protected (see Ogus 1999, pp. 412–7).

From the 2000s onward, things have changed. Although the EU has plunged into the field of liability insurance since the 1970s, the majority of statutory interventions on tort law have been adopted after the turn of the century (see below, section “The EU’s Piecemeal Approach”). In the same period, books on comparative law of European tort law started to multiply (Infantino 2012; Bussani and Werro 2009; Bussani 2007b; van Dam 2006; Brüggemeier 2004; Bussani and Palmer 2003; Zimmermann 2003b; van Gerven et al. 2000; von Bar 1998, 2000), as did studies on the costs and benefits of tort law harmonization (van Boom 2009; Bussani 2007a; van den Bergh and Visscher 2006; Wagner 2005; Faure 2003; Hartlief 2002; Banakas 2002). Two scholarly projects aiming at drafting a text for a future European tort law – the *European Group on Tort Law*, established under the auspices of the German reinsurance company Munich Re, and the *Study Group on a European Civil Code*, generously financed by the EU – published their results in 2005 and 2006, respectively (see below, section “Striving for Harmonization: The European Group on Tort Law and the Study Group on a European Civil Code”). In 2010, the *European Centre of Tort and Insurance Law*, closely affiliated to the *European Group on Tort Law*, distributed the first issue of the *Journal of European Tort Law* (de Gruyter).

Despite the different perspectives taken by the initiatives, the EU institutions and the scholars who participate in striving-for-harmonization projects agree that simplifying the current diversity of national tort laws is an aim worth pursuing. The reasons put forward to support such a view are many. First, a single European tort law regime is thought to contribute toward achieving the wider goal of a common area for free movement of goods, services, capital, and people. Simplifying the current European tort law patchwork would avoid the risk of inhibiting the mobility of persons

and goods by the different conditions for liability and amount of compensation (Magnus 2002, pp. 206–207). It would minimize the risk of European businesses’ forum shopping in search for the jurisdiction with the lowest quality and liability standard, thus fending off pressures on states to engage in a race to the bottom (Faure 2003, pp. 47–51). It would also increase the attractiveness of the European market to non-European economic operators: Europe would be more business-friendly if economic actors only had to tackle one unified regime, instead of 29 (1 supranational and 24 national) (van Boom 2009, p. 438; Reg. n. 864/2007, whereas 16, 20). Additionally, it has been emphasized by the EU institutions that a harmonized scenario would facilitate courts’ handling of trans-boundary torts, decrease the length and complexity of transnational litigation, and guarantee more uniformity between judicial outcomes (Reg. n. 864/2007, whereas 16, 20). Last but not the least, the EU Commission has underlined that a single tort law framework would allow insurers to better operate throughout the European Union and to establish and provide services in a freer manner (European Commission Directorate-General for Internal Market and Services 2007, pp. 47–8) – an observation echoed by scholars, who have stressed that the fragmentation of European tort law has a number of detrimental consequences for insurance enterprises operating within the single market (Wagner 2005, 1274).

This institutional and academic enthusiasm has not been supported by everyone. Many have criticized the claims upon which the very idea of harmonizing tort law is founded. They have pointed toward the lack of empirical evidence supporting the allegation that fragmentation of tort laws affects the free circulation of people and goods (van den Bergh and Visscher 2006, pp. 513–6; Faure 2003, pp. 44–7) and the establishment and movement of business in Europe (Wagner 2005, p. 1272; Hartlief 2002, p. 228). In this light, the true beneficiaries of the harmonization process would not be people and business but insurers and scholars themselves. On the one hand, tort law harmonization would reconcile the many legal surroundings to which European insurance companies currently adjust to and

would therefore lower insurers' barriers to entering and/or operating in multiple jurisdictions (Wagner 2005, p. 1274). On the other hand, the pro-harmonization movement would provide many scholars with a suitable avenue to enhance their own prestige, enabling them to promote their career, collect funding, and attract social, legal, and economic attention to their work (Infantino 2010, pp. 48–9; with regard to harmonization of laws in general, see Schepel 2007, pp. 187–8; Hesselink 2004, pp. 688–9).

Many have reminded that the benefits that harmonizing tort law may provide should be weighed against its possible costs, such as the difficulty in changing laws, the suppression of local preferences, and the abolition of any regulatory competition (van den Bergh and Visscher 2006, pp. 513, 516–8; Faure 2003, pp. 36–7, 59–66). There is indeed little doubt that for any harmonization plan to be effective, the new uniform tort law rules would have to be subject to the unifying control of one Supreme Court (Bussani 2007a, p. 377) and would need to be coordinated with the notions and solutions offered in other fields of law, including civil procedure, criminal matters, administrative remedies, and constitutional provisions (Bussani 2007a, pp. 365–8, 377; Faure 2003, pp. 45–6). Even if judicial review and coordination with the broader legal framework could be guaranteed, any top-down harmonization effort would put into circulation rules foreign to the tradition and heritage of some, if not all, legal traditions involved. Lack of familiarity with the new rules and their underpinning rationales, as well as the possible path dependency on deep-rooted local traditions, could lead to the defeat of any harmonization project (Bussani 2007a, pp. 373–7). Moreover, it has been noted by many that the idea of harmonizing European tort law would have to face the same issues that are raised by any harmonization endeavor at the European level. Such issues include policy and linguistic choices, the (lack of) competence of the EU institutions to harmonize private law in general, the political legitimacy of the drafters, and the feasibility and desirability of a European code in general (Giliker 2009, pp. 268–72; Bussani 2007a, pp. 371–3; Magnus 2002, pp. 208–212).

This is not the place to align with either one or the other side of the debate. The following pages will simply try to review how the EU institutions and scholars have contributed to the tort law harmonization discourse. Let us start with the EU's role.

The EU's Piecemeal Approach

According to the EU treaties, the EU does not have the general and comprehensive power to intervene in the field of tort law. The only competence assigned to the EU by the treaties with regard to tort law concerns the responsibility of Member States and of the EU itself in cases where they breach their obligations under the treaties (see Arts. 260(1), (2), and (3) and Art. 340(2) of the Treaty on the Functioning of the European Union). The task of judging the compliance of Member States and the EU institutions with the treaties is entrusted to the Court of Justice of the European Union, whose case law on this point has played an important role in shaping the states' liability across Europe (van Gerven 2009, pp. 32–3).

Yet the EU has, through time, carved out new competencies in the realm of tort law. It has done so through the adoption of statutory laws – mostly directives – aimed at harmonizing those segments of tort law that were deemed to most often cross national boundaries and/or affect the development of the internal market the most (von Bar 1998, pp. 401–7). The trend started in the 1970s with the directive on liability insurance, the objective of which was to establish a harmonized insurance system to facilitate people's free movement and guarantee compensation to persons injured in a Member State different from their own (Council Directive 73/239/EEC of 24 July 1973 on the coordination of laws, regulations, and administrative provisions relating to the taking-up and pursuit of the business of direct insurance other than life assurance, now replaced by the Commission Directive 2009/139/EU of 25 November 2009 on the taking-up and pursuit of the business of insurance and reinsurance). In 1985, a directive on products liability pursued consumer safety

through the adoption of a strict liability regime for producers of defective products (Council Directive 85/374 of 25 July 1985 on the approximation of the laws, regulations, and administrative provisions of Member States concerning liability for defective products). In 2004, two other directives introduced a common framework, respectively, for compensating crime victims (Council Directive 2004/80 of 29 April 2004 relating to compensation to crime victims) and for protecting the environment on the basis of the “polluter pays” principle (European Parliament and Council Directive 2004/35/CE of 21 April 2004 on environmental liability with regard to the prevention and remedying of environmental damage). On the assumption that cross-border externalities may be countered by harmonized rules of private international law, the EU enacted a regulation in 2007 enabling conflict of law rules to designate the law applicable to transnational tort claims (Regulation (EC) No. 864/2007 of the European Parliament and of the Council of 11 July 2007 on the law applicable to non-contractual obligations). In 2013, the European Commission issued a recommendation on a set of common, nonbinding principles for collective redress mechanisms (Commission Recommendation of 11 June 2013 on common principles for injunctive and compensatory collective redress mechanisms in Member States concerning violations of rights granted under Union Law). The last act of the EU statutory series on tort law was a directive adopted (not yet formally) in 2014 and aimed at removing practical obstacles to compensation for victims of infringement of the EU antitrust law (Directive of the European Parliament and of the Council on certain rules governing actions for damages under national law for infringements of the competition law provisions of Member States and the European Union).

Some of the abovementioned reforms have apparently enjoyed a remarkable success, both within and outside the EU borders. Compulsory vehicle insurance, for instance, is now a reality throughout the EU. The directive on products liability has inspired many legislators around the world who preferred to follow the newly

established EU model rather than the US model (Reimann 2003). Yet the actual effectiveness of the abovementioned EU laws is overall much debated. To illustrate, studies carried out on the insurance sector have pointed out that the liability regimes underlying compulsory insurance for traffic accidents are still diverging remarkably among European jurisdictions (van Dam 2013, p. 459). In a similar vein, it has been noted that, despite the external success of the products liability directive, the convergence created by the act has been minimal, and the rate of litigation grounded on the EU-branded products liability regime has remained incredibly low (Reimann 2014; Howells 2008).

Many reasons have been put forward to explain the limited effect of the EU’s harmonizing strategy in the field of tort law.

A first explanation points to the piecemeal approach taken by the EU. The EU institutions have up to now kept themselves far from any intervention in the general architecture of substantive tort law. They implicitly assume that tort law can be divided into a core of general rules to be left to national jurisdictions and “special” rules where the EU legislation can effectively intervene (von Bar 1998, p. 408). Yet the “special” rules can only be applied within and through the framework of the general rules. This is why planting the seeds of a special EU discipline in national tort law frameworks risks being a bad strategy for achieving the goal of minimizing the differences between national tort laws (van Gerven et al. 2000, p. 10; von Bar 1998, p. 408).

Such a risk is increased by both the contradictory character of the EU patchwork of tort law statutory provisions and by the absence of a court entrusted with a general competence over the interpretation of those provisions (Koziol 2007, pp. 5–6; Koch 2007, p. 109; van den Bergh and Visscher 2006, p. 11; Faure 2003, pp. 56–7). Contradictions often arise within the EU legal framework itself, because the EU institutions lack, among other features, a common vocabulary and a standard terminology capable of summarizing the different notions arising from the European linguistic and legal plurality. Contradictions may

also appear within national legal contexts where the EU rules are to be implemented, due to the lack of homogeneity between the EU and national languages, concepts, and rules (von Bar 1998, pp. 387–9).

All the above flaws are said to be worsened by the very use of the directives as the EU's main legislative tool (Koziol 2007, pp. 5–6; Koch 2007, p. 109; von Bar 1998, p. 410). Directives have the virtue of flexibility, i.e., of guaranteeing that each state can adapt the EU acts into its national categories, but the flip side is that frequently the outcomes of the process of implementation diverge greatly due to the tendency of Member States to replicate the traditional features of their legal system into the implemented rules. Thus, directives may result in intensifying legal differences as opposed to supporting uniformity (van Gerven et al. 2000, pp. 9–10; for some concrete examples, see Infantino 2010, p. 58).

Resorting to regulations rather than directives is only a limited cure. With regard to the only regulation so far adopted in the tort law field – Reg. n. 864/2007 on the law applicable to non-contractual obligations – it has been noted that many factors might hinder its uniform application. Divergence, for instance, may stem from the lack of agreement on the meaning of notions, such as “tort claim,” “injury,” “direct,” and “indirect” consequences (Hay 2007, pp. 139–40, 144, 149). Differences may also arise from the well-known tendency of national jurists to interpret foreign law in light of their national notions, categories, and rules of law or to even apply to transnational cases their own national law, no matter what the conflict of law criteria says (Fauvarque-Cosson 2001, p. 412).

Scholarly Endeavors

The above considerations led many scholars to pave their own way toward a truly common European tort law.

Aims and methods of these endeavors are very dissimilar from one another. There are associations, such as the *Pan-European Organisation of*

Personal Injury Lawyers (PEOPIL), whose purpose is the promotion of judicial cooperation between the European jurisdictions in personal injury litigation (see peopil.com). There are scholars who collect, translate, and make available cases from different European jurisdictions, on the assumption that the ability of European courts to engage in exercises of legal comparison when deciding cases might be the right path to achieve a truly, long-term harmonizing effect (Markesinis 2003, pp. 156–176; see also the database at utexas.edu/law/academics/centers/transnational/work_new/; a similar enterprise is carried out by the *Institute for European Tort Law* with its EURO TORT database, atctil.org/ectil/EuroTort.aspx). Two closely connected Austrian-based institutions – the *European Centre of Tort and Insurance Law* and the *Institute for European Tort Law* – provide a forum for research on comparative tort law and a venue for publication of up-to-date information and commentary about European tort law. The two institutions (which also support the *European Group on Tort Law*) organize an Annual Conference on European Tort Law every year, update a database of European case law on tort (see the EURO TORT database mentioned above), and publish many series on tort law and a peer-reviewed journal (the *Journal of European Tort Law*) (for more information, see ectil.org and etl.oecaw.ac.at).

Some projects, such as the *Ius Commune Casebooks* and the *Common Core of European Private Law*, are focused on the need for improving knowledge about the EU's legal systems. Other groups, such as the *European Group on Tort Law* and the *Study Group on a European Civil Code*, have engaged in ascertaining solutions that may best regulate certain legal problems and in codifying those solutions in the text of a would-be European code.

Given the breadth and significance of their work, it is the last four initiatives we mentioned that we will focus our attention on. We will begin with the striving-for-harmonization enterprises and then move on to those whose pivotal aim is building and developing better knowledge of European private laws.

Striving for Harmonization: The European Group on Tort Law and the Study Group on a European Civil Code

As anticipated, two scholarly groups that have thus far attempted to draft a text for a would-be codification on European tort law: the *European Group on Tort Law* and the *Study Group on a European Civil Code*.

The former group was established in 1992 within the Viennese *European Centre of Tort and Insurance Law*, whose main sponsor is the German reinsurance company Munich Re (for more information, see egtl.org and ectil.org). From 1992 to 2005, the group accomplished many studies, the results of which have been collected in a series called *Principles of European Tort Law* (PETL), published by Kluwer Law International (Widmer 2005; Rogers 2004; Magnus and Martín Casals 2004; Spier 1998, 2000a, b, 2003; Koch and Koziol 2002; Magnus 2001; Koziol 1998). Each volume gathered national reports and comparative results of an inquiry carried out on a specific tort law topic (e.g., causation, fault, wrongfulness, strict liability, etc.). Contributors were asked to describe the legal treatment of the assigned topic in their country by responding to some theoretical issues and by solving concrete cases; the editors then summarized the results (European Group of Tort Law 2005, pp. 14–16). The outcomes of the research were used as a starting point for drafting the PETL, which were published in 2005. The PETL are divided into ten chapters: Basic Norm, Damage, Causation, Liability Based on Fault, Strict Liability, Liability for Others, Defences in General, Contributory Conduct or Activity, Multiple Tortfeasors, and Damages (for a general overview of the contents of the PETL, see Oliphant 2009; Koch 2007, 2009; van Boom and Pinna 2008; Koziol 2007; van den Bergh and Visscher 2006; Zimmermann 2003). The group is currently working on a new edition.

The other project committed to shaping a would-be legislative text was the *Study Group on a European Civil Code*, founded in 1998 by Professor Christian von Bar. The *Study Group* has the more general purpose of drafting a European code on the whole of private economic law

(von Bar 2001). In the *Study Group's* view, the preparatory work on a European code had to be performed by scholars, who are the only ones endowed with the necessary expertise to conduct the essential basic research and to set up rules unaffected by the particularities of national interests; the legislator's role could begin only once the academic work of selecting the *Principles of European Law* (PEL) was completed (von Bar 1999). In 2006, the drafting of the tort law book for the would-be European code was completed. The *Principles of European Law on Non-Contractual Liability Arising out of Damage Caused to Another* were first issued online on the group's website at sgecc.net and then included, with minimal modifications, in the *Draft Common Frame of Reference* prepared by the *Study Group* for the European Commission in 2008 and officially published by Sellier in 2009. The PEL are composed of seven chapters: Fundamental Provisions, Particular Instances of Legally Relevant Damage, Accountability, Causation, Defences, Remedies, and Ancillary Rules (von Bar 2009; for a general overview of the PEL contents, see Oliphant 2009; Blackie 2009; Blackie 2007; Blackie 2003 p. 133).

The intention of both the above groups was to supply the European (and national) legislator (s) with a possible basis for a new codification. To accomplish this goal, the groups neither looked for the rules most widely accepted across European countries, nor did they select, among the existing rules, the ones deemed most suitable for Europe. Instead, the groups sought what was the “best” solution to tort law problems, regardless of whether this solution reflected principles already established within any European jurisdiction (von Bar 2009, pp. 229–38; European Group of Tort Law 2005, p. 15).

On many issues, the drafters of the PETL and of the PEL clearly agreed about what the “best” solution for Europe would be. Both the texts take fault as the general basis for liability (cp. Arts. 4:101 PETL and 1:101(1) PEL) and complement it with vicarious liability rules for employers (Arts. 6:102 PETL and 3:201 PEL) and parents/supervisors of minors and mentally disabled persons (Arts 6:101 PETL and 3:104 PEL). In the

PEL as well as in the PETL, not all interests of the plaintiffs are worthy of the same legal protection. While there is no doubt about the abstract recoverability of losses deriving from the infringement of life, bodily and mental integrity, human dignity, liberty, and property (cp. Arts. 2:102 PEL and 2:201–3, 2:206 PETL), in both the texts compensation of pure economic loss is restricted (cp. Arts. 2:101(2)–(3) PETL with 2:204–5, 2:207–8, 2:210–1 PEL). The PETL as well as the PEL stress that compensation is the primary function of tort liability (cp. Arts. 10:101 PETL and 6:101 PEL). Moreover, both the PETL and the PEL emphasize the need to take into consideration special features of tort law conflicts that can actually be brought under examination, calling for an application of their rules carefully tailored to all the relevant circumstances of the case (cp., for instance, Arts. 2:105, 3:103, 3:201, 4:102, 4:201, 10:301(2) PEL and 2:101, 3:103(3), 5:301, 6:101(4), 6:103, 6:202 PEL).

Yet in many other cases the PETL and the PEL consistently diverge from one another as to what the “best” solution is. For instance, under the PETL, minors and persons with mental disability are not exonerated from personal liability (Art. 4:102 PETL), while special rules are designed by the PEL for personal liability of minors and persons with diminished mental capacity (Arts. 3:103 and 5:301 PETL). There is no uniformity between the texts as far as no-fault liability is concerned. The PETL set forth a presumption of fault for evaluating harmful entrepreneurial activities (Art. 4:202(1) PETL) and impose strict liability on whoever engages in an abnormally dangerous activity “for damage characteristic to the risk presented by the activity and resulting from it” (Art. 5:101 PETL). By contrast, the PEL provide no presumption of fault but rather establish a set of strict liability regimes, specifically tailored to compensate the damage caused by the dangerous state of an immovable property (Art. 3:202 PEL), animals (Art. 3:203 PEL), defective products (Art. 3:204 PEL), motor vehicles (Art. 3:205 PEL), and dangerous substances or emissions (Art. 3:206 PEL).

As far as damage is concerned, the PETL give minimal guidance regarding the criteria for the

(un)recoverability of pure economic losses (Art. 2:102(4) PETL), but are more detailed as to the conditions under which redress for pain and suffering may be justified (Art. 10:301 PETL). By contrast, the PEL devote six articles to the requirements for compensation of pure economic losses (Arts. 2:204–5, 2:207–8, 2:210–1 PEL; the circumstance led many scholars to observe that the PEL open the liability floodgates for pure economic loss to an extent that goes far beyond the accepted standards in most Member States: see Zimmermann 2009, p. 496; Wagner 2009, pp. 234–7; Eidenmüller et al. 2008) and do not restrict compensation for pain and suffering and impairment of the quality of life (Art. 2:101(4) (b) PEL).

According to the PETL, even when an interest is deemed worthy of protection, the judge has to take into account all the relevant circumstances of the case in order to determine whether or not the recovery is undesirable in light of other public interests or the necessary “liberty of action” of the defendant (Art. 2:102(6) PETL). To instill a similar pro-defendant flexibility, the PEL adopt a wider approach, allowing the judge to not only verify whether, in light of all the circumstances of the case, granting compensation would be “fair and reasonable” (Art. 2:101(2)–(3) PEL) but also to relieve the faulty defendant from liability when “liability in full would be disproportionate to the accountability of the person causing the damage or the extent of the damage or the means to prevent it” (Art. 6:202 PEL).

The list of divergence between the PETL and the PEL could go further. For instance, the PEL, but not the PETL, authorize the plaintiff to take precautionary measures so as to reduce the risk of damages (Art. 1:102 PEL) and to claim that the defendant disgorge the profits she has obtained from the wrongdoing (Art. 6:101(4) PEL). The PETL, differently from the PEL, allow the judge to disregard trivial damage, regardless of whether another remedy is available to the victim (Art. 6:102 PEL).

Such amount of disagreement between the two texts is indeed not surprising, considering the uncertainty that exists, even among law and economics scholars, as to what tort law model

(s) would best fit the European legal framework (van den Bergh and Visscher 2006, pp. 513–4, 521–40). Rather than the foreseeable differences of opinion between the PEL and the PEL on these issues, what is more interesting to note, in our perspective, is a critique of the methodology and policy agenda that both the projects have embraced. While both the PETL and the PEL, as scholarly by-products, have the merit of offering a concrete basis for the debate on the prospects of European tort law, their future implications are much less straightforward. Leaving aside the doubts about the legitimacy of the jurists involved in these initiatives to act as legislators (Wagner 2005, pp. 1283–4), as well as any concern on the feasibility and desirability of a European codification of tort law (on which see above, section “The Variety of European Tort Laws”), what should be stressed here is that the adoption of either set of rules would require practitioners, judges, and scholars in national jurisdictions to become accustomed to a completely new tort law pattern and to develop methods and techniques that would, more or less, be foreign to their legal tradition. At least in the short run, the lack of such traditional accumulation of methods and techniques would likely drive jurists not accustomed to that pattern to keep relying on their own legal culture and on their traditional repertoire of solutions and technicalities. Thus, a fundamental objection to the top-down imposition of, the not-so-common, principles is the risk of perpetuating the divergence that the harmonization process is precisely aimed to reduce (Bussani 2007a, p. 369).

Building Knowledge: The *Ius Commune* Casebooks for the Common Law of Europe and the Common Core of European Private Law Projects

Aware that solutions to the above issues are critical, other scholars pursued another path. “Knowledge-building” enterprises share the common view that top-down harmonization cannot be undertaken without the collateral support of bottom-up initiatives. Therefore, the real instrument and target for those who are seeking the establishment of a truly European tort law should

be the development of a common legal culture, based on as much knowledge as possible of the legal experience of each European jurisdiction.

Irrespective of the uses to which knowledge may be applied, which may or may not include the pursuit of legal harmonization, knowledge building is both the starting point and the final aim of two projects whose scope is broader than the ones we just examined, insofar as their focus goes beyond tort law only. These two projects are the *Ius Commune Casebooks for the Common Law of Europe* and the *Common Core of European Private Law*.

The *Ius Commune Casebooks* initiative was launched in 1994 by Professor Walter van Gerven with the aim of producing a collection of casebooks covering each of the main fields of European law (on the aims and methods of such a project, see van Gerven 2002, 2007; Larouche 2000, 2001; van Gerven 1996). The long-term purpose of the *Ius Commune* project is to “uncover common general principles which are already present in the living law of the European countries” for the benefit of European students (van Gerven et al. 2000, p. 68). In this view, the casebooks are primarily conceived as teaching materials to be used in the curricula of law schools in order to promote a common European education.

As of now, seven volumes have been published by Hart (van Erp and Akkermans 2012; Micklitz et al. 2010; Beale et al. 2010; Schiek et al. 2007; Beatson and Schrage 2003; van Gerven et al. 1998, 2000), and many are forthcoming, on issues as diverse as labor law, law and art, constitutional law, judicial review of administrative action, conflicts of law, and legal history (see casebooks.eu). Two volumes concerning tort law have already been published (van Gerven et al. 1998, 2000); one of them (van Gerven et al. 2000) is under review for the second edition. Every casebook, whose table of contents and materials are partly accessible on the project’s website, collates legislation, excerpts from books, articles, and, above all, cases from various jurisdictions – mostly from France, England, and Germany, which are considered as representative of the main European legal families. Materials

from other legal systems are included in the casebooks only if they present an original solution when compared to the above legal systems. These materials are accompanied by introductory and explicatory notes, stressing the similarities among European legal systems, and the impact of the EU law “as a driving force towards the emergence of a new *ius commune*” (see casebooks.eu/research.php). The casebooks are written by a task force composed of academics representing what are deemed to be the “main” European legal families (van Gerven et al. 2000, vi-vii). A distinctive feature of the project is that each task force member, instead of dealing solely with his/her national legal system, is charged with writing an entire thematic chapter, even if it refers to legal systems different from his/her country of origin or of education. This distribution of work guarantees that the final outcome is not a patchwork of national reports but rather the genuine result of a truly comparative effort.

The *Common Core of European Private Law* project, led since 1994 by Professors Mauro Bussani and Ugo Mattei, has a different target audience, methodology, and primary goal. The initiative aims to unearth what is common, and what is not, between the EU Member States’ private laws, in order to provide a reliable description of the actual state of the art of the European multi-legal framework (for a general overview of the project, see Bussani et al. 2009; Bussani and Mattei 1998, 2000, 2003, 2007; Kasirer 2002, p. 417; Bussani 1998).

Unlike the *Ius Commune Casebook* project, which emphasizes the solutions given by the legal systems considered to be leading or paradigmatic, the *Common Core* project focuses equally on all the EU national legal systems. The research carried out under the *Common Core* initiatives is published as volumes in a dedicated series by Cambridge University Press (although some books have also been published by Stämpfli and Carolina Academic Press). Of the fifteen volumes published so far (Hondius and Grigoleit 2014; van der Merwe and Verbeke 2012; Brüggemeier et al. 2010; Hinteregger 2008; Cartwright and Hesselink 2008; Möllers and Heinemann 2008; Bussani and Mattei 2007; Pozzo 2007; Graziadei

et al. 2005; Sefton-Green 2005; Werro and Palmer 2004; Kieninger 2004; Bussani and Palmer 2003; Gordley 2001; Zimmermann and Whittaker 2000), five deal with civil liability issues, such as recoverability of pure economic losses (Bussani and Palmer 2003), protection of personality rights (Brüggemeier et al. 2010), boundaries of strict liability (Werro and Palmer 2004), ecological damage (Hinteregger 2008), and pre-contractual liability (Cartwright and Hesselink 2008). Two other volumes on tort law, causation, and products liability, respectively (see common-core.org), are under preparation.

On the shoulders of Rudolf B. Schlesinger’s and Rodolfo Sacco’s path-breaking research (Schlesinger 1968, 1995; Sacco 1991), the *Common Core* adopts a method based on the so-called factual approach as underpinned by the dissociation of legal formants. At the very foundation of the *Common Core*’s efforts, there is the following set of assumptions. Legal systems are not always made up of a coherent set of principles and rules, as domestic jurists tend to assume. What the rules say often does not relate to what the very same rules translate to in practice. Legal actors at work in the same legal system – the bar, the bench, scholars, lawmakers, insurers, bureaucrats, and so on – do not always offer the same account and interpretation of what legal rules are. Further, circumstances that are officially ignored and considered to be irrelevant in the application of the law often operate in secrecy, slipping in silently between what law is said to be and how it is actually applied (Bussani and Mattei 1998, pp. 343–5).

The need to delve into the depths of legal systems, and to obtain comparable answers from jurists from different jurisdictions, led the *Common Core*’s General Editors to adopt questionnaires as their key methodological tool. The research work develops as follows: when a topic is chosen, the person charged with the task of editing a volume on that particular topic drafts a factual questionnaire and distributes it among the national rapporteurs participating in the project. The questionnaire has a sufficient degree of specificity as to require respondents to address all the factors that have a practical impact on the legal

system they are analyzing. This method also guarantees that national responses surface how apparently identical black-letter rules may in fact produce different applications. The use of fact-based questionnaires also allows understanding whether and to what extent solutions depend on legal rules outside the private law field, such as procedural mechanisms, administrative schemes, or constitutional provisions, or on other factors, e.g., policy considerations, economic reasons, and social values, affecting the law-in-action level (Bussani and Mattei 1998, pp. 351–4). Responses to the questionnaires are publicly analyzed, discussed, compared, and subsequently collected by the topic editor of a volume in a book, which is published in the *Common Core* series.

There are many data that attest to the success of these two initiatives. The *Ius Commune* casebooks have been adopted in the curricula of European law faculties and have been quoted by national courts in their domestic tort law opinions (see some illustrations on casebooks.eu/project/aim/). *Common Core* volumes are widely cited by judges and scholars across and beyond European jurisdictions, and some of them have even been translated in languages other than English (see, e.g., Bussani and Palmer 2005). Yet, besides the number of books published and the amount of quotations these books get, the most important outcomes of the *Ius Commune* and the *Common Core* projects lie in the acculturation processes they trigger and in the transformations they help to bring about in European legal systems. These processes and transformations run deep in European legal cultures – so deep that their effects, although not easy to quantify in the short run, promise to be the most long-lasting ones in the long run.

Conclusions

Any assessment of the harmonization perspective in a given field must indeed take into account the time factor.

There can be no doubt that European tort laws, as defined by statutory texts, judicial precedents, and/or scholarly writings, and ultimately applied by courts to the disputes brought before them,

display many lines of convergence. Yet tort law does not live in parliaments, law firms, courts, and law books only. It also lives “in the shadow” of the official systems of adjudication. It lives in the offices of insurance companies, which provide coverage for damages caused by the insured or third parties. It lives in people’s notions about injury and risk, responsibility, and justice, determining people’s conducts in day-to-day activities and their litigation/non-litigation choices once a wrong has occurred. Tort law lives in languages, concepts, and images associated with law in mass-generated popular culture – newspapers, television, movies, and novels – as well as in public debates about what values should be protected and promoted, at what costs, and at whose expense (Bussani and Infantino 2015; Oliphant 2012). This stratified set of individual and mass responses to injury, risk, and responsibility does not stand still. Its different constituents may change over time, moving in the same place at different speeds and in different directions (Bussani 2007a, pp. 369–70).

When dealing with the prospects of a soon-to-be harmonized European tort law framework, one should take time seriously. Harmonization efforts – whether hard or soft, legislative or scholarly driven, or aimed at immediate uniformity or at knowledge building – usually trigger a variety of transformations in the layers of a legal system. The time, speed, and direction of these transformations can widely diverge and are usually very difficult to predict, as is the way in which the transformations affecting one layer will interact with other layers of the system. The only dynamic that can be easily foreseen is that the more abrupt the requested change and the larger its departure from the legal culture where it should take place, the greater would be the time and cost needed by that legal system to adjust to the new framework – no matter how efficient it would be.

Harmonization: Consumer Protection

Franziska Weber

Faculty of Law, Institute of Law and Economics,
University of Hamburg, Hamburg, Germany

Abstract

This contribution gives an overview of law and economic works on consumer protection. It does so by taking three complementary angles: (1) assessing harmonization efforts regarding

consumer protection in Europe, (2) presenting selected topics of substantive consumer law, and (3) analyzing the European consumer law enforcement from an economic point of view.

Synonyms

Consumer law; Consumer legislation; Consumer policy

Introduction

Consumer protection laws refer to a set of rules aimed at stipulating and guarding consumers' rights. It is a challenging field and requires knowledge of different legal areas (contract law, tort law, regulatory law, competition law, etc.) because consumer problems by nature lie at the borderline of private/public problems and social/commercial ones. Substantive consumer laws encompass public and private law, which is why redress is necessarily made to both public and private enforcement instruments. Whereas harmonization efforts at the European level have historically primarily concerned substantive consumer laws, European legislation increasingly aligns procedural laws also.

This contribution is structured as follows: Section “[The Legal Approach and Its Economic Analysis: Research on Consumer Behavior](#)” gives a short introduction to research into consumer behavior. Section “[Harmonizing the European Consumer Law](#)” starts with an economic analysis of harmonizing consumer law throughout Europe. It then brings into focus selected topics of consumer protection more specifically. On top of the substantive law dimension, a condensed economic analysis of the European consumer law enforcement is presented. Section “[Conclusion](#)” concludes.

The Legal Approach and Its Economic Analysis: Research on Consumer Behavior

The consumer movement started developing in the 1960s and 1970s. Advocates of this movement

I wish to thank Roger van den Bergh for the valuable comments on an earlier version of this contribution.

took the consumers' weaker position for granted and, therefore, strongly favored strengthening consumers' rights. Up until today the paternalistic consumer protection argument continues to be used when it comes to justifications for passing legislation in the field of consumer law (Micklitz et al. 2010, p. 1).

Whereas the term protection hence implicates a paternalistic element, an economic insight into consumer markets is the fact that increased consumer protection comes at the cost of higher product prices (Faure 2008). Typically an intervention in the market will lead to costs for the producer, such as increased expectancy of damage payments. It is therefore straightforward that these costs will be reflected in the product's price. Consequently, any legal intervention needs to be justified by the existence of a market failure. The most commonly occurring market failure in consumer law is information asymmetries, such as quality uncertainty (Akerlof 1979; Van den Bergh 2007a). The debate on consumer policy in law and economics in elaboration of the neoclassical approach has taken three different theoretical angles: information economics, new institutional economics, and behavioral economics (Rischkowsky and Döring 2008). In information economics the notion of asymmetric information is prevalent. The consumer is regarded as unable to appropriately perceive quality differences (Stigler 1961; Stiglitz 2000). A lack of information on the consumers' side and the resulting information costs impact on the consumers' decision-making process. This may be cured by providing consumers with more information. New institutional economics, on the other hand, acknowledges that the pure provision of information is not sufficient and calls for regulation of certain institutions (e.g., contracts). It expands the focus to looking at institutional arrangements in place to cure information asymmetries and deals more closely with specific rules. New institutional economics is more broadly concerned with transaction costs (Williamson 1975) – not only information costs – that impact market transparency and consumer behavior. Another core notion of this stream of economics relevant also to consumer behavior is that of “bounded rationality”

(Simon 1957). According to this concept individuals, even if presented with all necessary information, are unable to correctly process it due to the limited capacity of the human brain to do so. Behavioral economics challenges the rational choice theory even more radically by showing that consumers – even when exposed to complete information – cannot successfully process it (Kahneman et al. 1982; Sunstein and Thaler 2009). Consumers are shown to systematically deviate from rational behavior. Behavioral economics provides insights on how consumers perceive and use available information and act in the presence of choice. Perception is dependent on consumers' internal constraints in the form of cognitive, emotional, and situational factors (Luth 2010). A notion put forward within behavioral economics is that of libertarian paternalism (Thaler and Sunstein 2003) – a form of paternalism that protects people from making bad choices by not employing coercion.

Consumer research is being carried out within all of these disciplines, with behavioral economics being the most recent and most popular one (Vandenberghe 2011; Sunstein and Reisch 2014). In the last years policy-makers and law-makers at the European or Member State (MS) level and also, for instance, in the United States start to take more account of such evidence. Whereas insights are regarded as very valuable to understand real consumer behavior, some challenges need to be overcome still before strong normative conclusions may be drawn. There is, for instance, evidence of cognitive biases pointing in opposite directions; furthermore behavioral economics keeps lacking a framework to systematically use its insights for policy-making (Vandenberghe 2011). It is an unresolved matter how general conclusions can be drawn from a limited set of experiments. Note should be taken of the fact that marketing research has long dealt with better understanding consumer behavior (for an early contribution, see Kotler 1965).

Given its importance in the European context, it should be mentioned that much of the consumer law research is carried out from the angle of comparative law and economics, as the name suggests the intersection between comparative law and the

economic analysis of law (e.g., Faure et al. 2009; Kovac 2011; Weber 2014).

Harmonizing the European Consumer Law

Once an economist has identified a market failure, this paves the way to some type of – cautious or intrusive – legal intervention. One decision to be taken is, consequently, the type of legal intervention – e.g., imposition of information duties. A layer additionally complicating the nature of passing consumer laws in Europe is the availability of various lawmakers: For the European Union (EU), the competences are generally either situated at the MS level or at the Union level. Not all Union legislation, furthermore, leads to the same degree of unification within Europe. A starting point would be whether a regulation, directive, or other instrument is chosen; legal instruments can aim at different levels of harmonization.

The legal basis stipulating law-making competences does not necessarily coincide with economic theory on the desirable level of law-making powers at all times. The trade-off between centralized and decentralized decision-making has been assessed from the point of view of “economics of federalism” (Oates 1972) and “regulatory competition” (Ogus 1999; Van den Bergh 1994, 2000, 2002), also specifically for the European consumer law (Van den Bergh 2007b; Faure 2008). The concepts can be used to give meaning to the principle of subsidiarity (Van den Bergh 1994) and identify the adequate level of law-making. Competition between different laws is regarded as desirable as it enables citizens to choose the jurisdiction according to their preferences (Tiebout 1956). Differences, furthermore, may facilitate learning between the states. Decentralized rule-making may have advantages in terms of being better able to tailor legislation to preferences, and local authorities may have an information advantage regarding local specificities (Van den Bergh 2007b). Reasons to harmonize on the other hand are the need to internalize interstate externalities, the potential danger of a race to the bottom, economics of scale,

and the reduction of transaction costs. Another factor to be taken into consideration is political distortions that depend on the strength of lobby groups at the various levels (Van den Bergh 2002).

The findings will differ for the area of law considered. Regarding the case of consumer protection laws, the discussion on the adequate level of law-making and the need for harmonization was recently steered up again by the Consumer Rights Directive (Directive 2011/83/EU of the European Parliament and of the Council of 25 October 2011 on consumer rights, OJ L 304, 22.11.2011, pp. 64–88). According to the original draft proposal, four directives previously aiming at minimum harmonization were to be changed into maximum harmonization (Faure 2008). (The directives concerned are Directive 85/577/EEC on contracts negotiated away from business premises, Directive 93/13/EEC on unfair terms in consumer contracts, Directive 97/7/EC on distance contracts, and Directive 1999/44/EC on consumer sales and guarantees.) This original proposal triggered heavy criticism by law and economics scholars (Van den Bergh 2007b; Faure 2008), providing strong arguments against full harmonization and instead pleading in favor of diversity: mainly because preferences of consumers in the MS diverge a lot, not least based on differences in income levels. The final text of the Consumer Rights Directive does not claim maximum harmonization as strongly as the first draft. It is said to having been watered down to “some kind of quite undefined ‘targeted’ (i.e., partial or incomplete) full harmonisation” (Gomez and Ganuza 2012). Its content concerns primarily information duties for distance, off-premises, and other contracts and the right of withdrawal for distance and off-premises contracts (see recital 9).

Substantive Law Dimension

There is a growing body of research discussing the costs and benefits of consumer protection laws (Cseres 2012). Recent collections of law and economics work on contract law were published in the context of discussing the Draft Common Frame of Reference (Wagner 2009; Larouche and Chirico 2010); some contributions deal more specifically with consumer protection clauses

(Luth and Cseres 2010 and for the Common European Sales Law, Bar-Gill and Ben-Shahar 2013).

Much of consumer law is written as mandatory laws; other consumer protection provisions are stipulated as default rules. From a legal point of view, there is no clear normative stance identifying a preference for one type over the other; apparently the protection aspect plays an important role. From a law and economics point of view, certain costs and benefits of both types of rules have been identified. It is crucial that mandatory rules prevent “sharper deals forgone” by consumers who would have abstained from enjoying certain types of costly consumer protection rules; however, they are prohibited by law from doing so (Mackaay 2013, p. 423). This factor, on top of the costs of enacting and enforcing such a rule, needs to be weighed against potential benefits. For default rules the costs are different as opting out of the default is possible and may lead to costs (Mackaay 2013). In addition, the default may end up being unsuited or deviation may practically be impossible. Law and economics literature has dealt extensively with the question of what the default should be (Ayres 2012). In the first wave of this literature, the view prevailed that the default rule should be the one that the majority would have chosen as this would reduce total costs. A second stream of literature concerned a debate on whether there is such a thing as a penalty default or information-forcing default. Such a rule basically punishes the non-deviating party by, for instance, granting his/her a high interest rate only if he/she does not reveal certain information. Lately, not least under the influence of behavioral law and economics, the debate has turned toward the design of different default rules – personal default rules or those enabling active choice (Sunstein and Reisch 2014) – and the notion of “altering rules,” i.e., the rules that set out how one can deviate from the default option (Ayres 2012). Cognitive biases are used to illustrate how certain types of formulations and conditions to deviate from the default affect behavior. Some rules can be regarded as “sticky,” i.e., choice is only an illusion. These findings play in the context of all types of mandatory and default rules that may be relevant for consumer protection.

Standard contract terms in consumer contracts have specifically attracted scholar’s attention. There are empirical studies confirming that consumers do not read these terms (e.g., Bakos et al. 2014) and publications discussing the consequences of this insight for policy-making (Luth 2010). An empirical study regarding the content of such terms in the context of software companies, for instance, confirms a bias toward terms favoring the contract writer – in this case the software company (Marotta-Wurgler 2007). The basic market failure asserted is that of an information asymmetry (Schäfer and Leyens 2010). Due to the consumer not being able to observe the terms and condition’s quality, quality may overall decrease, driving good terms out of the market. A consequence that may be drawn is that a judicial control of standard terms is desirable for certain types of contracts.

Further research concerns the costs side of a right of withdrawal (Eidenmüller 2011). One such cost may be a potential moral hazard problem (Rekaiti and Van den Bergh 2000). Unsurprisingly, given that a lot emphasis is put on the problem of information asymmetries between consumers and the opposite party, information disclosure rules are an important aspect of consumer protection law (Beales et al. 1981; Eisenberg 2003; De Geest and Kovac 2009, and from a comparative law and economics point of view: Kovac 2011). Law and economics has furthermore dealt with the topic of warranty contracts and their different functions being that of insurance, a quality signal and acting as an incentive to provide high quality (Emons 1989; Werth 2011). The classical consumer topic “unfair commercial practices” is dealt with from an economic point of view by Gómez (2006). Within the scope of this short overview, it is not possible to set out all the research that has been carried out (see for a broader overview Cseres 2012). Suffice it to say that also advertising and banking laws have attracted scholarly attention.

Law Enforcement Dimension

From an economic viewpoint, the threat of enforcement steers people’s behavior, more particularly, their incentives to obey the law. The

interplay between substantive laws and their enforcement forms the incentives and deterrents that induce law-abiding behavior. Law and economics scholars traditionally discuss enforcement matters from the angle of *Becker's* deterrence theory developed for criminal law (Becker 1968). According to the deterrence theory, a rational wrongdoer can be induced not to violate the law if the sanction for a potential wrongdoing (multiplied by the probability of detection and conviction) is at least as large as the benefit he/she could obtain from committing the wrong. Meanwhile, this approach has been expanded to law enforcement more broadly.

There are a number of different enforcement mechanisms at play in consumer law, and group litigation is a powerful procedural tool. Law and economics scholarship is long to realize that, for instance, classical public and private enforcement schemes clearly each have a number of economic strengths and weaknesses (Shavell 1993; Van den Bergh 2007a; Faure et al. 2009; Weber 2014). Crucial economic factors at play when assessing whether individuals will initiate a lawsuit or report a wrong are the following: Due to “rational apathy” an individual will not act if the costs of doing so outbalance his/her benefits, for instance, when harm is very small and the investment to enforce the law is costly (Van den Bergh 2007a). If societal harm is nevertheless large, no action may be taken because of a divergence between the individual and social incentive to sue (Shavell 1997). The other extreme is “frivolous lawsuits” that are not based on merits and socially not desirable. Another possible distortion of incentives concerns “free-riding” problems. This problem can occur if in certain situations, in which many victims suffer from a law infringement but all gain as soon as one of them sues, it is efficient for everybody to wait for someone else to sue and then profit from the result (Van den Bergh and Visscher 2008a, p. 14). As mentioned information asymmetries are the core market failure in consumer law, e.g., unobservable characteristics of a consumer good. For the enforcement side it is furthermore true that they are one of the key triggers of litigation. Law enforcement mechanisms/procedures are therefore also discussed regarding the extent to which

they mitigate these asymmetries by generating information. Investigative powers are a main means to achieving this. Continuing to think along the lines of enforcer's incentives to carry out tasks as desired, literature discusses capture as an incentive problem, meaning the exertion of influence on public administration that leads to public officials pursuing, e.g., industry interests (Ogus 1994, p. 57). This concept can be expanded to other enforcers. Principal-agent problems are another matter discussed in this literature. In these relationships the principal (e.g., a client) cannot fully control the quality of the agent's (e.g., lawyer's) performance (Shavell 1979). The basis for any principal-agent problem is an information asymmetry between two parties, which can lead to moral hazard. Lastly, two additional types of costs are decisive: Error costs refer to courts taking mistaken decisions. Error costs can generally be divided in two groups: Error I costs are those that occur when an individual who is guilty might mistakenly not be found liable (“mistaken acquittal”). Error II costs on the other hand occur if an innocent individual might mistakenly be found liable (“mistaken conviction”). Administrative costs then refer to all costs incurred by having a particular enforcement system in place, which in reality is challenging to measure.

By way of example, private law enforcement, if litigation costs are substantial, may suffer from people being rationally apathetic, and depending on the remedy that is sought, “free-riding” may be an issue. Public law enforcement scores highly when it comes to reducing information asymmetries by having investigative and monitoring powers in place. It is generally differentiated between judges that are less likely to be captured compared to public officials, self-regulatory institutions, or certain group representatives. Group litigation, if designed well, is able to reduce rational apathy problems, same as “free-riding” problems. However, capture may be an issue, same as a more complex principal-agent structure and high administrative costs. Criminal law on the other hand may deter even judgment-proof wrongdoers, those that are insolvent, by unique sanctions such as imprisonment (Bowles et al. 2008). Again, administrative costs are

presumably high, same as investigative powers would be. Error costs are discussed as a concern in particular for administrative law enforcement as opposed to criminal law enforcement. In conclusion the optimal solution might be to create a mixture of public and private enforcement that draws upon their comparative advantages (Van den Bergh 2007a; Faure et al. 2009) – the so-called optimal mix of public and private enforcement. Furthermore this mix needs to vary for different sectors of consumer law. Therefore recent research attempts to design optimal enforcement mixes concretely for certain consumer violations by arguing along the lines of the different established economic criteria (e.g., safety laws (Van den Bergh and Visscher 2008b), misleading advertising and package travel (Weber 2014)).

The allocation of enforcement between various mechanisms is one of four crucial parameters of law enforcement, according to law and economics literature (Shavell 1993). The other three are the optimal sanction (injunction, administrative fine, criminal fine), the optimal timing of the intervention (ex ante monitoring and/or ex post enforcement), and the optimal governmental level – either centralized or decentralized – to house the enforcement powers (see also section “[Harmonizing the European Consumer Law](#)”). Needless to say, the parameters are heavily interlinked and cannot be discussed in isolation.

At the EU level various legal initiatives in the context of consumer law enforcement are ongoing: alternative dispute resolution and online dispute resolution (legislative proposal for a Directive of the European Parliament and of the Council on alternative dispute resolution for consumer disputes and amending Regulation (EC) No 2006/2004 and Directive 2009/22/EC (Directive on Consumer ADR), Brussels, 29.11.2011 COM (2011) 793 final and proposal for a Regulation of the European Parliament and of the Council on online dispute resolution for consumer disputes (Regulation on Consumer ODR), Brussels, 29.11.2011 COM(2011) 794 final 2011/0374 (COD)), same as collective redress. (See Commission Recommendation of 11 June 2013 on common principles for injunctive and compensatory collective redress mechanisms in the Member

States concerning violations of rights granted under Union Law OJ L 201, 26.7.2013, p. 60–65, Communication from the Commission “Towards a European Horizontal Framework for Collective Redress”, C(2013) 3539/3.) The EU has, furthermore, strengthened the public law dimension with the Regulation on Consumer Protection Cooperation. (See Regulation (EC) No 2006/2004 of the European Parliament and of the Council of 27 October 2004 on cooperation between national authorities responsible for the enforcement of consumer protection laws (the Regulation on Consumer Protection Cooperation).) These initiatives found their echo in scholarly writing (Keske 2010; Van den Bergh 2013; Wagner 2014) and also stressing the need to take due account of MS’s differing traditions when suggesting EU-wide legislation (Weber 2014). Implementation costs of the EU legislation vary for each MS depending on the prevalent enforcement tradition (Ogus 1999; Faure 2008). Countries are “path dependent” which is why deviating from their tradition may incur costs that need to be weighed against benefits of a new law.

Conclusion

Increasingly, law and economics scholars are looking into consumer protection matters. Research thereby takes various angles. One aspect concerns the questionable desirability of harmonizing consumer laws throughout Europe. Secondly, scholars assess typical consumer law topics, such as standard contract terms or duties of information disclosure from an economic perspective. Thirdly, research is ongoing regarding the fine-tuning, mixing, of different enforcement mechanisms in consumer law. Consumer research is increasingly carried out within behavioral law and economics. Furthermore studies take due account of the importance of comparative law which is particularly crucial in the context of EU law-making. It is important to suggest new European legislation in awareness of existing enforcement traditions in the MS.

In terms of future research, two main challenges can be identified: Firstly, the question on

how far behavioral insights should be translated into policy- and law-making needs answering, and a framework to doing so would need to be established. Secondly, when passing consumer legislation at the European level, it is crucial to identify each time to what extent harmonization is indeed desirable. In this overall cost-benefit assessment, an important factor to be considered is implementation costs which stem from countries' path dependencies. This is a key to avoiding inadequate European legislation.

Harmonization: Legal Enforcement

Katalin J. Cseres

Amsterdam Centre for European Law and Governance, Amsterdam Center for Law and Economics, University of Amsterdam, Amsterdam, The Netherlands

Abstract

While harmonization and convergence of national substantive laws are well advanced in the European Union, a similar convergence and harmonization of the procedural rules and institutional frameworks has not taken place. The implementation, supervision, and enforcement of EU law are left to the Member States in accordance with the so-called national procedural and institutional autonomy. This “procedural competence” of the Member States means that the Member States have to provide remedies and procedures governing actions intended to ensure the enforcement of rights derived from EU law.

Harmonized substantive rules are implemented through diverging procedures and different kinds of enforcement bodies, but this decentralized enforcement challenges the coherent and uniform application of EU law. In an enforcement system where Member States apply divergent procedures, may impose a variety of sanctions and remedies administered by various actors the effectiveness of EU law, effective judicial protection and effective law administration may be at risk. This chapter analyzes the development of EU law

concerning law enforcement and takes a critical look at the EU's aim to harmonize the national procedural rules when EU law is enforced. It will examine the question of which legal basis can be used in order to harmonize procedural rules, whether harmonizing procedural rules would be more efficient than the existing legal diversity and the economics of harmonization will be applied to assess the top-down harmonization by the EU and comparative law, and economics is applied to evaluate the bottom-up voluntary harmonization of the Member States.

Introduction

The implementation, supervision, and enforcement of EU law are left to the Member States in accordance with the so-called national procedural and institutional autonomy. This “procedural competence” of the Member States means that the Member States have to provide remedies and procedures governing actions intended to ensure the enforcement of rights derived from EU law, provided that the principle of equivalence and the principle of effectiveness are observed. (*Case 33/76, Rewe-Zentralfinanz eG and Rewe-Zentral AG v Landwirtschaftskammer für das Saarland (Rewe I)*, [1976] ECR 1989, para 5.) Competence allocation in the European multilevel governance is politically sensitive (Bakardjieva-Engelbrekt 2009; Cafaggi and Micklitz 2009; Van Gerven 2000), and as such, it has been extensively discussed in the literature and in the case law of the European courts (Jans et al. 2007). (*Case C-410/92, Johnson* [1994] ECR I-5483, para. 21; *Case C-394/93, Unibet (London) Ltd and Unibet (International) Ltd*. [2007] ECR I-2271, para 39; *Joined Cases C-430/93 and C-431/93 Van Schijndel and van Veen* [1995] ECR-I4705; *Joined cases C-295/04 to C-298/04 Manfredi v Lloyd Adriatico Assicurazioni SpA and Others* [2006] ECR para 62.) This discussion has mainly addressed the competence allocation between the Member States and the EU and the increasing influence of EU law and policy with regard to procedural and remedial autonomy (Delicostopoulos 2003; Kakouris 1997;

Lenaerts et al. 2006; Prechal 1998; Trstenjak and Beysen 2011; Reich 2007; Van Gerven 2000). It has, however, not addressed the question to which authorities of the Member States allocate regulatory powers for the enforcement of EU law and how they organize and structure these enforcement agencies in their national administrative law system. (Institutional autonomy is the Member States' competence to design their own institutional structure and allocate regulatory powers to public administrative agencies that enforce EU law (Verhoeven 2010). In *International Fruit Company II*, the CJEU has stated that

[A]lthough under Article 5 of the Treaty the Member States are obliged to take all appropriate measures, whether general or particular, to ensure fulfilment of the obligations arising out of the Treaty, it is for them to determine which institutions within the national system shall be empowered to adopt the said measures [...] when provisions of the Treaty or of Regulations confer power or impose obligations upon the states for the purposes of the implementation of Community law, the question of how the exercise of such powers and the fulfilment of such obligations may be entrusted by Member States to specific national bodies is solely a matter for the constitutional system of each state

Joined cases 51–54/71 International Fruit Company II 15 December 1971: [1971] E.C.R. 1107. paras 3–4.)

While harmonization and convergence of substantive laws are well advanced, a similar convergence and harmonization of the procedural rules and institutional frameworks have not taken place. In the following sections, first the development of EU law concerning law enforcement will be examined, and then a critical look is taken at the EU's aim to harmonize the national procedural rules when EU law is enforced. First, it will be examined whether legally it is feasible, i.e., what legal basis can be used in order to further harmonize procedural rules. Second, it will be examined whether harmonizing procedural rules would be more efficient than the existing legal diversity. The economics of harmonization will be applied to assess the top-down harmonization by the EU and comparative law, and economics is applied to evaluate the bottom-up voluntary harmonization of the Member States.

Development of EU Law on Law Enforcement

In the EU Member States, highly convergent and harmonized substantive rules are implemented through diverging procedures and different kinds of enforcement bodies. This decentralized enforcement poses a challenge to the coherent and uniform application of EU law. In an enforcement system where Member States apply divergent procedures and may impose a variety of sanctions and remedies administered by various actors, the effectiveness of EU law, effective judicial protection (Articles 6 and 13 of the ECHR, Article 47 of the Charter of fundamental rights of the European Union which has now been reaffirmed in Article 19(1) TEU), and effective law administration may be at risk. In EU competition law, for example, it has been questioned whether consistent policy enforcement and the effective functioning of the European Competition Network require a certain degree of harmonization of procedures, resources, experiences, and independence of the NCAs (Bakardjieva-Engelbrekt 2009; Cengiz 2009; Gauer 2001; Frédéric 2001). Similarly, in consumer law, the Unfair Commercial Practices Directive 2005/29 has allowed the Member States to establish their own specific enforcement systems. The national enforcement regimes are very diverse: some Member States have predominantly private enforcement; others rely predominantly on public bodies. In accordance with the principles of procedural and institutional autonomy, the Member States can entrust public agencies or private organizations with the enforcement of consumer laws, enabling those institutions to decide on the internal organization, regulatory competences, and powers of public agencies (Balogh and Cseres 2013). The variety of national enforcement architectures is remarkable in light of the far-reaching harmonization goal of the Directive. Moreover, the broader institutional framework comprising of locally developed enforcement strategies may further differentiate the Member States' enforcement models.

The following two sections will first examine which developments have taken place toward

harmonization of law enforcement in the EU and then examine the economic rationale of such harmonization.

Europeanizing Law Enforcement

The influence of EU law on Member States' procedures and remedies of law enforcement has been gradually growing since 1992 (de Moor-van Vugt 2011) and has been intensified when enlargement to the Central and Eastern European countries in 2004 took place (Bakardjieva-Engelbrekt 2009). According to Nicolaides, enforcement became a priority area of EU policy with the process of enlargement due to the fact that, first, the CEECs emerged from many years of communism and they had to build institutions that were accountable to citizens and functioned in very different environments than in the past. Second, EU integration has progressed, and the impediments in the internal market were found in administrative weaknesses and incorrect implementation of EU law. Third, the legal body of the *acquis* expanded considerably, especially in the area of internal market, and it made proper enforcement key to make the single market work (Nicolaides 2003, pp. 47–48).

De Moor-van Vugt has identified patterns in the Europeanization of law enforcement. She shows that as from the early 1990s, the Commission began to monitor the Member States' enforcement of EU law due to insufficient implementation of EU law resulting in fraud with EU structural funds (de Moor-van Vugt 2011). As a result, the Commission implemented a stricter policy which limited the Member States' procedural autonomy and obliged them to comply with the principles of sincere cooperation, non-discrimination, and effectiveness (de Moor-van Vugt 2011). The CJEU's judgment in *Greek Maize* opened the way for the Commission to lay down obligations for the Member States in consequent directives and regulations that concerned subsidies in order to take appropriate measures in case of infringements of EU law. (Since the CJEU's judgment in C-68/88 *Greek Maize* the Member States are required by Article

4 (3) TFEU to take all measures necessary to guarantee the application and effectiveness of EU law. While the Member States remain free to choose the appropriate enforcement tools, they must ensure that infringements of EU law are penalized under conditions, both procedural and substantive ones, which are analogous to those applicable to infringements of national law of a similar nature and importance and which, in any event, make the penalty *effective, proportionate, and dissuasive*. Case 68/88 *Commission v Hellenic Republic*, Judgment of the Court of 21 September 1989, I-2965, paras 23–24.) De Moor-van Vugt demonstrates that the same pattern of Europeanizing national enforcement models has been followed by the EU in several other sectors such as agriculture, environmental law, financial services, and sector regulations such as telecom and energy (de Moor-van Vugt 2011, p. 72).

The process of Europeanizing enforcement was well visible in the modernization of EU competition law from the late 1990s and further since Regulation 1/2003 entered into force in 2004. The improvement of cross-border enforcement laid also at the heart of the Regulation 2006/2004 on consumer protection cooperation. (Regulation (EC) No 2006/2004 of the European Parliament and of the Council of 27 October 2004 on cooperation between national authorities responsible for the enforcement of consumer protection, O.J. L 364/1, 9.12.2004.) This Regulation has set up an EU-wide network of national enforcement authorities and enabled them to take coordinated action for the enforcement of the laws that protect consumers' interests and to ensure compliance with those laws.

Similarly, in the liberalized network industries, the EU gradually extended the EU principles of *effective, dissuasive, and proportionate sanctions* as formulated in the case law of the European courts to a broader set of obligations and criteria for national supervision in EU legislation. The liberalization of state-owned enterprises has been accompanied by the obligation for Member States to create regulatory agencies in order to maintain elements of public control and to provide reassurance of independence from government in

creating a level playing field for new entrants (Gorecki 2011; Scott 2000; Thatcher 2002).

Europeanizing market supervision (Ottow 2012) in the liberalized network industries also obliged Member States to establish independent national regulatory agencies with core responsibilities for monitoring markets and safeguarding consumers' interests (Micklitz 2009). Member States have strengthened the role of regulatory agencies and have empowered them with a growing number and diversity of regulatory competences. In law enforcement, a shift has taken place from the state to individuals and their collectives and also a shift from judicial enforcement to more administrative law enforcement (Cafaggi and Micklitz 2009).

Harmonization of Law Enforcement

The above-described process of Europeanizing law enforcement in the Member States through the harmonization of national procedural rules has been driven by the EU Commission. However, EU harmonization of civil or administrative procedures faces problems of legitimacy (e.g., private enforcement of competition law in fact is a question of national private law rules, contract, tort, and corresponding civil procedural rules. Case C-453/99 *Courage v. Crehan* ECR [2001] I-6297) because the Commission lacks the competence and a clear legal basis to harmonize procedural rules. In accordance with the so-called national procedural autonomy and the principle of subsidiarity, the Member States have the competence to lay down private law consequences of EU law infringements as well as the administrative procedures. The Member States provide for remedies to effectuate damage actions, and it is for the national courts to hear cases. (The CJEU has consistently held that

[I]n the absence of Community rules governing the matter, it is for the domestic legal system of each Member State to designate the courts and tribunals having jurisdiction and to lay down the detailed procedural rules governing actions for safeguarding rights which individuals derive directly from Community law, provided that such rules are not less favourable than those governing similar domestic

actions (principle of equivalence) and that they do not render practically impossible or excessively difficult the exercise of rights conferred by Community law (principle of effectiveness)

Joined cases C-295/04 to C-298/04 *Manfredi v Lloyd Adriatico Assicurazioni SpA and Others* [2006] ECR para 62; Case 33/76, *Rewe-Zentralfinanz eG and Rewe-Zentral AG v Landwirtschaftskammer für das Saarland (Rewe I)*, [1976] ECR 1989, para 5, Case C-261/95 *Palmisani* [1997] ECR I-4025, para 27, Case C-453/99 *Courage and Crehan*, par. 29.)

In accordance with Article 5 TEU, the Union is only empowered to act within the competences conferred upon it by the Treaty. With regard to the harmonization of procedural rules, one could turn to Article 114 TFEU, which forms the legal basis for harmonization measures when such measures have as their objective the establishment and the functioning of the internal market. For example, the Public Procurement Remedies Directives were issued on this legal basis. (Council Directive 89/665/EEC of 21 December 1989 on the coordination of the laws, regulations, and administrative provisions relating to the application of review procedures to the award of public supply and public works contracts [1989] OJ L 395/33; Council Directive 92/13/EEC of 25 February 1992 coordinating the laws, regulations, and administrative provisions relating to the application of Community rules on the procurement procedures of entities operating in the water, energy, transport, and telecommunications sectors [1992] OJ L 76/14.) However, this Article has been strictly interpreted by the EU courts, and it can be applied only when it can be proved that without the harmonization measures, the functioning of the internal market would be endangered and competition distorted. The CJEU, among others, said that the goal of the Commissions' intervention has to be precisely stated by explaining the actual problems consumers face in the internal market and the actual obstacles to the free movement principles as well as the distortions of competition. In *Germany v. Parliament and Council*, the ECJ has explicitly said that

a measure adopted on the basis of Article 100a of the Treaty must genuinely have as its object the

improvement of the conditions for the establishment and functioning of the internal market. If a mere finding of disparities between national rules and of the abstract risk of obstacles to the exercise of fundamental freedoms or of distortions of competition liable to result there from were sufficient to justify the choice of Article 100a as a legal basis, judicial review of compliance with the proper legal basis might be rendered nugatory. (Case C-376/98 *Germany v. Parliament and Council* [5 October 2000] ECR I-8419, para 84; Two years later in the 'Tobacco Labelling' judgment when applying the same arguments it approved the adoption of the Tobacco Labelling Directive on the basis of Article 95 EC and it thereby reaffirmed its interpretation of Article 95 as a legal basis for measures of harmonization. Case C-491/01 *British American Tobacco v The Queen* [2002] ECR I-; Directive 2001/37 on Tobacco Labelling OJ 2001 L194/26 paras 60–61)

Accordingly, the Commission has to precisely define the legal problems by providing clear evidence of their nature and magnitude, explaining why they have arisen and identifying the incentives of affected entities and their consequent behavior.

Since the Amsterdam Treaty Article 81 TFEU can be applied as the legal basis for harmonization of civil procedural law, this legal basis can be used with regard to civil matters which have cross-border implications and in so far as common rules are necessary for the functioning of the internal market. It could be argued that even though this legal basis concerns civil procedural measures, it could be applicable also to administrative procedural law (Eliantonio 2009, p. 4).

Both Article 114 and 81 TFEU require a justification for procedural harmonization measures by showing that the functioning of the internal market is at stake, namely, that the direct effect of substantive EU law might be at risk and market competition would not take place on equal terms, unless at least some minimal requirements concerning procedure were upheld in all Member States, then there would be adequate grounds to support the introduction of harmonized remedies in national courts. Accordingly, in order to decide upon the necessity of EU harmonization measures in the field of procedural law, the negative effects of diverging judicial remedies for European integration should be estimated.

Procedural differences in the Member States could be justified by their impact on business

actors. Competition would be distorted when business actors have to reduce their business in a certain Member State because of the difficulty that they might encounter in enforcing EU law. Consequently, the benefits of harmonized procedural rules may be transparency and legal certainty which might be appreciated especially from the perspective of economic policy and competition.

It is the next section that will discuss these economic arguments of harmonization and legal diversity.

The Economics of Harmonization

As mentioned above, in EU law, the harmonization process is governed by the principles of subsidiarity and proportionality. These principles have been argued to entail a cost-benefit analysis of legislation and require to minimize transaction costs (Van den Bergh 1994). The economics of harmonization discusses the costs and benefits of legal diversity and harmonization. It addresses the optimal level of intervention by applying the economic theory of federalism as extended to the theory of regulatory competition.

The idea that decentralized decision making may contribute to efficient policy choices in markets for legislation was first formulated by Tiebout in his seminal article on the optimal provision of local public goods (Tiebout 1956). (This economic theory argues that local authorities have an information advantage over central authorities, and, therefore, they are better placed to adjust the provision of public goods to the preferences of citizens. Under certain strict conditions, the diffusion of powers between local and central levels of government favor a bottom-up subsidiarity. The economics of federalism deals with the allocation of functions between different levels of government. Tiebout argued that buyers “vote with their feet” by choosing the jurisdiction which offers the best set of laws that satisfy their preferences. The economics of federalism rests upon a number of assumptions. When the “Tiebout conditions” are fulfilled, competition between legal orders will lead to efficient outcomes. There has to be a sufficiently large number of jurisdictions among

which consumers and firms can choose. Consumers and firms enjoy full mobility among jurisdictions at no costs. Last, there are no information asymmetries, which on the one hand means that states have full information as to the preferences of firms and citizens, and on the other, suppliers of production factors must have complete information on the costs and benefits of alternative legal arrangements. Only in the presence of these information requirements will consumers and firms be able to choose the set of laws, which maximizes their utility or profit. Further, no external effects should exist between states and regions. There must be no significant scale economies or transaction savings that require larger jurisdictions.) Tiebout’s model has been extended to legal rules and institutions. The theory of regulatory competition applies the dynamic view of competition to sellers of laws and choice between legal orders offering a number of criteria to judge whether centralization or decentralization is more successful in achieving the objectives of the proposed legislation (Van den Bergh 1994, 1996, 2002). In this section, these criteria will be applied to the Commission’s harmonization proposals in order to consider the likely costs and benefits of top-down rule-making.

One reason to harmonize procedural rules is that these rules differ across countries that they may lead to adverse externalities for other Member States. Such negative spillover effects might be present with regard to different procedures as well. While such negative externalities can be internalized by harmonization, bargaining between the Member States can also solve this problem. According to the Coase theorem, when property rights are well specified, transaction costs are low and information is complete and bargaining can be an efficient solution (Van den Bergh and Camesasca 2001, p. 132).

Another reason in favor of harmonization is that different legal rules carry the risk of destructive competition. Such a “race to the bottom” development has often been linked and criticized as a result of competition among jurisdictions. It has been argued that competition among legal rules drives social, environmental, cultural, and other standards down. This argument has been

mainly embraced in international corporate law by making reference to the “Delaware effect.” However, the risk of such declining levels of standards has not yet been proved, and the little empirical evidence is not conclusive enough (Wagner 2005; Josselin and Marciano 2004, pp. 477–520; McCahery and Vermeulen 2005). Furthermore, international trade may even stimulate race to the top (Van den Bergh and Camesasca 2001, pp. 153–154). Gomez also argues that the outcome of such competitive process cannot be examined without taking into account the relative power of the affected groups (Gomez 2008). Such competition might not harm powerful and well-organized groups but could have different effects for small- and medium-sized enterprises and consumers.

A third argument often raised to support harmonization is to achieve scale economies and to reduce transaction costs. Transaction costs can be high when firms and consumers have to search and comply with different sets of national rules. In the case of uniform rules, the search costs of information could be saved, and complying with one set of rules can achieve scale economies. Uniform rules can guarantee more stable and predictable jurisprudence and considerably contribute to transparency and legal certainty.

In particular, it has been argued that business would profit from clear and transparent system in which they would be able to enforce their claims against public authorities all over Europe pursuant to the same procedural rules (Elia Antonio 2009, p. 6). This raised the question whether procedural harmonization may be pursued in a “compartmentalized” way for specific policy areas. With regard to the private enforcement of EU competition law, two remarkable suggestions were made. Both concern a separate harmonization of economic torts or in the present case economic administrative procedures. Heinemann proposed that general tort rules of the DCFR could be examined against the backdrop of the special needs of competition law (Möllers and Heinemann 2007, p. 377). Boom proposed a compartmentalized approach to work with the existing modest body of European tort law. By addressing the policy issues involved in each of these torts one by one, the

European Union can make harmonized tort law more attainable. He pointed out that a likely candidate for harmonization is the category of economic torts, such as the protection of intellectual property through tort law, liability for infringement of competition rules, and the liability for misleading advertising (Van Boom 2008, pp. 133–149).

However, transaction costs can be especially relevant for large firms operating in interstate commerce, the same might not hold for small- and medium-sized undertakings operating mainly in national markets or for consumers. Therefore, as mentioned above, the impact of such harmonization also has to be analyzed with having regard to the relative power of the affected groups.

Furthermore, while uniform rules help to maintain economies of scale, which is an important argument for centralization, but they can only be advantageous from an *ex ante* perspective, when neither the Member States nor the Community have as yet adopted certain legislation (Van den Bergh 1998). This is neither the case with regard to administrative or civil procedural rules, which are rooted in old legal traditions and characteristics of the different legal systems.

When all parties in one region have identical preferences, cost efficiency considerations might point to harmonizing through one single instrument that suits all. This is clearly in-line with the preferences of the business community as they are in favor of uniform rules. However, the preferences of consumers and public administration can significantly diverge. In fact, it has been argued that the legal systems of the Member States are built through habits, customs, and practices which dictate how law is going to be interpreted (Legrand 2002, p. 230), and that public law “has particularly deep roots inside a cultural and political framework” (Harlow 2002, p. 208). This is clearly the case with regard to enforcement bodies as these are a wide variety of institutions that enforce EU law in the Member States (Cseres 2013; Balogh and Cseres 2013).

Accordingly, the possibility of achieving a common procedural (administrative or civil) law in Europe is doubtful because the political conditions are missing and because the national legal

systems are based on very different conceptions (Eliantonio 2009, p. 8). The same is true for bridging the gaps between the various economic policies and institutional settings. Harmonization of administrative procedures might conflict with legitimate national interests, such as the need to protect fairness and efficiency in the administration of justice (Eliantonio 2009, p. 7). Due to these fundamental differences in national administrative procedures, it would be very difficult to agree on common rules for all 27 jurisdictions, and in fact, it has been argued that “a general codification could be achieved only by reducing the requirements to the level of a common denominator, in which case it would prove as a barrier rather than an asset for an effective and uniform enforcement of Community law” (Schwarze 1996, p. 832). Moreover, some Member States may prefer to implement criminal law procedures for the enforcement of most severe law violations as this is the case already in a significant number of Member States concerning consumer, environmental, or even competition law.

In sum, there are not sufficient economic arguments in favor of harmonization, but there are good economic arguments in supporting legal diversity. One such argument is that a larger set of legislations can satisfy a wider range of preferences which leads to allocative efficiency. The broad range of preferences can easily be seen behind the various different regulations on unilateral conduct, but it also holds for administrative procedures. Another argument is information asymmetries that support decentralization by maintaining the principle of subsidiarity and procedural autonomy. When information at local level is more valuable for rule-making and law enforcement, decentralization is more efficient. Competition between these legal rules has the advantages of a learning process. National laboratories produce different rules that allow for different experiences and that can improve the understanding of alternative legal solutions. (Justice Brandeis’ famous metaphor for states as laboratories of law reform and his plea for decentralization has been laid down in his dissenting opinion in *New State Ice Corp. v. Liebmann*, 285 US 262, 311 (1932).) These advantages are

relevant for both the formulation of substantive rules as well as law enforcement. Moreover, legal diversity and competition does not necessarily exclude harmonization. In fact, dynamic competition between legal rules can lead to voluntary harmonization which in turn can be more effective and successful than forced coordination of legislations. Instead of forced harmonization, the Commission could guarantee the conditions for regulatory competition and let this process work up to voluntary harmonization. These conditions could in fact be ensured within the various European networks of national regulatory agencies that were set up in the last decade.

Voluntary Harmonization

This section will analyze the underlying rationales of voluntary convergence by making use of insights from comparative law and economics.

Comparative law and economics compares and evaluates the law of alternative legal systems with the “efficient” model offered by economic theory (Mattei et al. 2000, pp. 506–507) (Mattei 1994). Comparative law and economics deals with “legal transplants” by measuring them with the tool of efficiency, and it offers an economic analysis of institutional alternatives tested in legal history (Komesar 1994). It “deals with the transplants that have been made, why and how they were made, and the lessons to be learned from this.” While it offers comparative lawyers the measuring tools of economics, it, at the same time, places the notion of efficiency in a dynamic perspective by offering a comparative dimension with concrete alternative rules and institutions (Watson 1978).

The insights of comparative law and economics offer a dynamic approach to study legal divergence and convergence and compare that against the benchmark of efficiency offered by economics. In order to explain convergence between different legal systems that depart from different points, it uses economic efficiency to evaluate changes that are so-called legal transplants in a legal system. Convergence between different legal rules toward an efficient model may take

place as a result of a legal transplant or as an outcome of a competitive process between different legal formants (Mattei et al. 2000, pp. 508–511). In the first case, legal transplants are implemented because they proved to be efficient in other legal systems. In the second case, convergence toward efficiency is the result of the interaction between different legal formants. So while legal transplants are governed by hierarchy, the second scenario is governed by competition among legal formants (Mattei et al. 2000, pp. 510–511).

In EU competition law, for example, the Member States voluntarily harmonized various elements of their national administrative procedures (European Competition Network 2013). Yet, this convergence exhibits some shortcomings in terms of the benchmark it uses and in terms of the methods to achieve convergence. First, convergence between the different national rules uses Regulation 1/2003 and some accompanying soft-law instruments as its benchmark. Thus, convergence so far took place through legal transplants imposed by the Member States and by in fact implementing similar procedural rules as those of the Commission's. The underlying reasons might be that once these rules and enforcement methods work effectively and efficiently in the hands of the Commission, they will prove successful in the hands of the NCAs as well. However, the efficiency of these rules and their comparative advantage vis-à-vis other national rules has neither been analyzed nor confirmed. Furthermore, the success of such legal transplants is not guaranteed in the different institutional frameworks of the Member States, where agencies often have to divide resources between several legislative competences. The actual outcome of enforcement depends heavily on the existing institutional framework (Cseres 2014a, b).

The influence of the institutional framework also plays a role in measuring actual law enforcement and in understanding why a certain legal rule proves to be successful or fails in different institutional contexts (Stiglitz 2002; North 1995, p. 13).

Despite the blueprint convergence of procedural rules, the NCAs could not or did not actually

enforce these rules due to certain constraints present in their institutional framework. The strengthened enforcement tools have not always delivered the expected results in actual enforcement. This is, for example, the case with regard to the power to investigate private premises (Commission Staff Working Paper, par. 202.). Similar experience has been found with regard to leniency programs which are often praised as the model for procedural convergence in EU competition law and a clear result of the cooperation mechanism within the European Competition Network (Cseres 2014a, b).

Convergence of national laws in EU competition law is also steered from the center by the Commission establishing the EU rules as the benchmark for harmonization (Cseres 2014a, b). While the Commission was seemingly decentralizing enforcement powers, in fact it has retained a central policy-making role but without a control mechanism.

Hate Groups and Hate Crime

Matt E. Ryan¹ and Peter T. Leeson²

¹Department of Economics, Duquesne University, Pittsburgh, PA, USA

²Department of Economics, George Mason University, Fairfax, VA, USA

Definition

Hate crimes are criminal offenses motivated by offenders’ animus toward their victims based on victims’ race, religion, sexual orientation, or other such characteristic. Hate groups are organizations of individuals whose organizing purpose is thought to reflect animus toward certain people based on their race, religion, sexual orientation, or other such characteristic.

The Economics of (Hate) Crime

Gary Becker (1968) pioneered the economics of crime by applying rational choice theory to analyze decisions to break the law. In his rendering, and in most of the enormous literature in the economics of crime following Becker, criminal activity is motivated by the prospect of material gain.

Although material gain undoubtedly motivates the vast majority of criminal behavior, it does not motivate all of it. One example of criminal behavior not so motivated is that which reflects “hate crime.” The Federal Bureau of Investigation defines such crime as “criminal offense against a person or property motivated in whole or in part by an offender’s bias against race, religion, disability, sexual orientation, ethnicity, gender, or gender identity.” A Neo-Nazi who vandalizes a Jewish synagogue because of his animus toward Jews, for example, commits a hate crime. As Gale et al. (2002) point out, hate crimes thus differ from most other crimes in that the perpetrator’s goal is not (at least in whole) to make himself better off, but rather to make his victim worse off.

Correlates of Hate Crime

The correlates of hate crime include at least two factors commonly found to be important determinants of crime more generally: unemployment and income. Medoff (1999), Gale et al. (2002), Ryan and Leeson (2011), and Curthoys (2013), for example, find a positive relationship between unemployment and the incidence of hate crime in the United States (though Green et al. 1998 and Mulholland 2013 find no consistently significant relationship). Similarly, Sharma (2015) finds that underemployment is a significant determinant of cross-caste crime in India, and Iparraguirre (2014) finds that “employment deprivation” is associated with more hate crime against older people in England and Wales. Medoff (1999) finds a negative relationship between wages and hate-crime incidence. And Gale et al. (2002) and Sharma (2015) find a positive relationship between the ratio of income of a targeted group to the

(presumed) targeting group and race-based and cross-caste crime, respectively.

A correlate of hate crime that may be more specific to this particular type of offense is the social perceptions of persons who are typically victims of hate crime. Hanes and Machin (2014), for example, find that the terrorist attacks of September 11, 2001 in the United States and on July 7, 2005 in London were associated with increased hate crimes against the Asian and Arab populations in England.

Do Hate Groups Matter?

The Southern Poverty Law Center (SPLC) defines hate groups as groups which “have beliefs or practices that attack or malign an entire class of people, typically for their immutable characteristics.” Among such groups, the SPLC counts the Ku Klux Klan, Neo-Nazi, White Nationalist, Racist Skinhead, Christian Identity, Neo-Confederate, Black Separatist, and “General Hate” groups. To a certain extent, a particular group’s status as a “hate group” may be a matter of debate. The SPLC, for example, considers “patriot groups” hate groups; however, it is questionable whether all such groups can be reasonably likened to the Ku Klux Klan, Neo-Nazis, or other such groups whose organizing purpose is clearly grounded in racial, religious, or some other such prejudice.

Since hate groups are those that malign (or are thought to malign) people based on their race, religion, sexual orientation, etc., an obvious question is whether the prevalence of such groups is an important determinant of criminal offenses committed against such people – hate crimes. Theoretically, the answer to this question is ambiguous. If an important activity of hate groups is the perpetration of crimes against hated classes, one would expect more hate groups to lead to more hate crime. Alternatively, hate groups may act as substitutes for, rather than complements to, hate crime. For example, if hate groups serve predominantly as outlets for individuals to congregate and “safely” vent their hatred of certain persons, which might otherwise manifest in the form of criminal acts against these persons, such

groups may displace hate crime with the hateful bluster. In this case, it is possible that more hate groups could lead to less hate crime.

Empirical examination of the relationship between hate groups and hate crime in the United States has delivered somewhat mixed results. Ryan and Leeson (2011), who consider the relationship between the number of hate groups and hate crime at the state level between 2002 and 2008, find no evidence that more hate groups lead to more hate crime. Mulholland (2013), who uses county level data between 1997 and 2007, finds that an active white supremacist group within a county is associated with an increased rate of hate crime in that county. Adamczyk et al. (2014), who also use county level data from 1990 to 2012, find that ideologically motivated homicides are more likely in counties with larger numbers of hate groups. Most recently, Larson and Brandt (2016) consider the number of Ku Klux Klan chapters in 72 combined statistical areas (CSAs) between 2006 and 2014 and find that while CSAs with a larger number of active Ku Klux Klan chapters experienced higher rates of racially motivated crime, they also experienced lower rates of religiously motivated crime.

Abstract

F.A. Hayek focused on many traditional economic questions, and also made important contributions to law and economics. His framework differed from Kaldor Hicks efficiency and the wealth maximization norm common among neoclassical law and economics scholars. But he talked about how the common law evolves and helps shape economic outcomes. Underlying this approach was Hayek's conviction that the essence of law is not created by the state, but rather pre-exists in the conventions and understandings within a community. Hayek argued that the role of the judge in a common-law system is to discover the law in the imminent consensus of norms and expectations. Hayek's work has

many implications for positive analysis and normative discussions of what judges should or should not do. To Hayek, the primary purpose of the law is not a wealth maximization problem, but to provide a stable institutional framework in a dynamic world that enables individuals to plan and coordinate.

Biography

Friedrich A. Hayek was born in Vienna in 1899 and won the economics Nobel Prize in 1974 for “pioneering work in the theory of money and economic fluctuations” and “penetrating analysis of the interdependence of economic, social and institutional phenomena.” After studying under Ludwig von Mises in the 1920s, Hayek had a series of debates with John Maynard Keynes about government's ability to manage the business cycle. In the 1930s and 1940s, Hayek joined Mises in a debate against those who argued that government should centrally plan the economy. He maintained that economic problems cannot simply be solved with a system of simultaneous equations. In “The Use of Knowledge in Society,” Hayek (1945) interpreted the role of prices in a market society as the most effective means of allowing people to use their knowledge of time and place to develop economic plans consistent with those of the rest of society. And Hayek described the market itself as a “discovery process” for generating that very knowledge. His best-selling work was *The Road To Serfdom*, where Hayek (1944) argued that even setting aside the fatal economic flaws, socialism and milder forms of government planning are incompatible with freedom in the long run. Much of this work amounts to a vindication of the notion of spontaneous order – patterns that emerge through human action but not human design. Hayek came to see that the notion applied just as well to the formation of law, thereby making an early contribution to the field of land economics. (This entry focuses on Hayek's contribution to law and economics. For a more comprehensive discussion of Hayek's thought, see Caldwell (2004).)

Innovative and Original Aspects

In the earlier part of his career, Hayek followed the Continental *Rechtsstaat* tradition – going back to Napoleon – where law is understood as statute-based, formally expressed rules. Hayek believed these rules should be forward-looking, well-articulated, and applied equally to all individuals. Such thought can be found in his *The Road to Serfdom* (1944) and *The Constitution of Liberty* (1960).

But Hayek came to shift his views radically, as can be seen in his three-volume series *Law, Legislation, and Liberty* (1973; 1976; 1979). Hayek underplayed the significance of the shift, viewing it as a move from a focus on “public” law to “private” law. Empirically, Hayek had now turned his attention to the common law of England from the Continental law. Analytically, and viewed from the outside, Hayek began breaking from the prevailing scholarly understanding of the ideal of law – and of law itself.

According to the later works of Hayek, not only was the common law a spontaneous order, the common law was analogous to the market process. Properly instituted, common law evolved according to the population’s changing expectations concerning disputes. In contrast, top-down civil law evolved based on legislators’ understanding of what rules best resolve disputes. Legislators attempt to institute detailed rules to anticipate all future legal circumstances. In common law, judges instead act on the facts of particular cases, but the unintended result of all such decisions is a body of law that not only coordinates most people’s expectations, but makes use of detailed, tacit, and local knowledge and promotes liberty. Another effect of the decentralized legal process is that abstract, coherent principles emerge. “In an ever changing society,” Hayek wrote, “judges must seek to find rules that will aim at securing certain abstract characteristics of the overall order of our society that we would like it to possess to a higher degree” (Hayek 1973, p.105).

The common law is not only abstract, but non-arbitrary, despite emerging without central design, as it aggregates knowledge implicit in the pre-

existing, commonly understood conventions of people in particular communities (Hume 1740, Book III, p.541; Hayek 1973, p. 162). To be sure, certain conventions needed for a society to thrive can be objectively identified: stability of ownership (property law), transference by consent (contract law), and protection of property (tort law). Such a perspective can be consistent with a natural law- or rights-based perspective where certain basic rights or side constraints, to use Robert Nozick’s language, exist. But within that basic framework, many of the specifics of legal procedures and law itself can be seen as evolving. Under the right conditions, a Darwinian process of competition among communities with differing bodies of law tends to lead law to converge away from systems that fail to protect investment and resource conflict toward systems that lead to peaceful cooperation (Zywicki 2000).

Hayek found further merit in common-law systems for making law predictable. Counter-intuitively, civil law, despite its greater verbal precision, provides less predictability. Common law works in this respect because people in any given community have an intuitive understanding of the rules reflecting their widely shared sense of what is just. Having this understanding, potential litigants can predict on their own how cases would be decided and can adjust their planning accordingly. They may not be able to articulate the rules (their knowledge of the law is tacit; Zywicki 1998), but regardless, their intuitive understanding means they often need not consult case law. In contrast, potential litigants in a civil-law system must often seek legal advice to learn the specifics of complicated rules.

Given that the rules constituting common law are difficult for litigants to articulate, it should be no surprise that the role of the judge is to discover conventions, not construct them. Such a judge considers the implicit consensus of norms and expectations in a given community and applies it to the facts in particular cases (Zywicki and Sanders 2008). A legislator, in contrast, considers what external standard should govern disputes. The body of judge-discovered law emerges spontaneously (Hayek 1973, p.118); the civil law arises by design. Hayek (1973, p.123) wrote,

“The difference between the rules of just conduct which emerge from the judicial process, the *nomos* or law of liberty—and the rules laid down by authority ... lies in the fact that the former are derived from the conditions of a spontaneous order which man has not made, while the latter serve the deliberate building of an organization serving specific purposes.” Put differently, common law “has never been ‘invented’ nor can it be ‘promulgated’ or ‘announced’ before hand” (1973, pp. 72, 118).

Hayek considers the common law’s discovery process as analogous to that of price discovery in markets (Zywicki and Sanders, 2008). The owner of a gas station, for example, must discover and articulate what price the consumer will pay for gasoline, based on the supply and demand resulting from the outcome of billions of individuals’ interactions. Similarly, a judge discovers and articulates the preexisting rules. Both the gas station owner and the judge engage in a process of trial and error.

Discovery of the law involves a search for what conventions govern the particular circumstances of time and place. The specific conventions evolve over time and differ across place because individuals’ needs for exploiting their local knowledge differ. But though the conventions differ, they reflect the underlying, universal, and nonarbitrary principles for resolving disputes and promoting coordination. As society becomes more complex, larger, and more heterogeneous, the need arises for someone to articulate the conventions. But the law itself is the consensus of principles and expectations, not the judges’ articulation of the consensus.

Beyond the advantage of allowing judges to discover legal rules, the decentralized process of law making ensures there is no central decision-maker for interested parties to capture who can then impose a rule that will generate long-term rents, thereby reducing the opportunity and incentive for rent-seeking litigation.

Despite all of the perceived advantages of the common law, Hayek ultimately saw room for legislatures to step in when common law reaches a “dead end.” The judge’s proper role is at most to articulate new rules within an existing framework of rules and expectations – not to alter expectations and amend the framework. To Hayek, the legislature’s proper role is to devise new rules

when existing rules have become obsolete or if rules inconsistent with a market economy emerge. In his ideal, the legislature should act consistently with the purpose-independent, abstract principles of the common law (*cosmos*) rather than transform it through command-oriented rules (*nomos*). So even though Hayek supported judges setting most precedents, he supported legislatures overseeing the process to remove bad precedents.

One could argue that a tension exists in Hayek’s thinking here. On one hand, Hayek saw the evolution of law as a discovery process akin to the market’s discovery process. But at the same time, he analogized the monopolistic court system to the market system. But given that markets are disciplined by profits and losses, can a monopolistic court system have similar discipline? Can such a system learn whether the rules are consistent with underlying principles and expectations without the aid of competition? Does his other analysis about markets as a discovery process logically imply that an effective legal system must require competition as well (Stringham and Zywicki 2011a, b)?

Impact and Legacy

Hayek’s work has many implications for positive analysis and normative discussions of what judges, or other government officials such as regulators, should or should not do. In a Posnerian normative framework, judges should evaluate the costs and benefits of different decisions or laws in general and implement those that maximize wealth. But a Hayekian framework stresses the knowledge problems that confront judges seeking to determine and implement the wealth maximizing decision or set of rules. A Hayekian framework also emphasizes the subjective nature of individual cost and choice and the challenges this provides for any judge seeking to ascertain the efficient rule in any scenario. In this sense, judges seeking to maximize societal wealth or Kaldor Hicks efficiency are in a similar position to any central planner seeking to allocate resources to optimize wealth. They lack the necessary information to weigh costs and benefits and choose what is best for society. Such logic also applies

to judges who wish to tweak the details of the law. For instance, a movement from contributory to comparative negligence may have implications not only for other elements of the tort system (such as liability rules or damages), but also contract law, procedure, and remedies.

The more neoclassical law and economics models also implicitly assume that the world is in equilibrium where the judge simply compares the end states of his possible decisions. A Hayekian influenced law and economics, in contrast, recognizes that the world is in a state of change as billions of consumers around the world seek to constantly adjust to millions of constant and simultaneous shocks. Such change affects basic economic conditions but can also disrupt contractual relationships and lead to conflict among individuals (Zywicki and Sanders 2008). In Hayek's perspective, equilibrium cannot describe the world in the abstract. Instead we should focus on the ability of individuals to mesh their plans at any given time and to form expectations about how parties will perform in the future.

In this view, the primary purpose of the law is not a wealth maximization problem, but instead to provide a stable institutional framework that enable individuals to plan and coordinate their affairs in a world of constant dynamism. A set of relatively stable and clear rules enable people to predict one another's behavior (Hayek, 1978). Relatively clear and stable rules create boundaries for property rights, and other legal obligations enable individuals to adapt their behavior to the ever-changing world that surrounds them. Adding a constantly changing legal system – even if in the name of “modernization” or “updating” – to this chaotic world could create uncertainty and undermine the ability of individuals to coordinate their plans in the face of constant need for adaptation.

Zywicki (1998) argues that getting rid of letting government constantly change or adjust the law actually allows ordinary people to have a greater degree of confidence in the content of the law without needing to consult lawyers or run across an unexpected legal obligation. It also enables radical decentralization of decision-making authority to individuals who have the tacit and local knowledge most relevant to the particular decision. Some law and economics

scholars influenced by Hayek focus on legal norms or even entire legal systems that clearly emerged without central design or even any government control. Bernstein (1992) and Ellickson (1991) show that New York diamond merchants and California farmers and cattle ranchers devise various rules and regulations to govern their behavior independent of what legislatures or government judges say. Benson (1990) argues that the entire law merchant was created by business people to meet their needs of exchange. Stringham (2015) highlights that in seventeenth century Amsterdam, eighteenth century London, and nineteenth century New York, complex financial contracts emerged even though government was not enforcing, or actively trying to prohibit, them. The rules that govern the most advanced markets in the world market emerged from the market. In a Hayekian law and economics perspective, the world is not an optimization problem that government planners, regulators, or judges evaluate and solve. Instead the world, including law itself, can be viewed as a spontaneous order.

Hedge Fund Activism in Corporate Governance

Alessio M. Paces

Erasmus School of Law, Rotterdam Institute of Law and Economics, Erasmus University
Rotterdam, Rotterdam, The Netherlands

Definition

Hedge fund activism is an important disciplinary mechanism in corporate governance. It consists in actions aimed to change the way a company is managed, without trying to gain control. Because

hedge funds aim to profit from these actions, this is called entrepreneurial shareholder activism.

A hedge fund campaign can only succeed if a majority of institutional shareholders supports it. The question whether hedge fund activism leads to inefficient short termism in corporate governance can only be answered by looking at which investors are decisive on such campaigns. Although the empirical evidence on this is still unclear, index funds seem to be decisive in most instances.

Because of their incentives, index fund managers cannot be trusted to make an informed decision about whether the company should be managed for the short term or the long term. It turns out that the optimal choice in this respect varies with the individual companies and with time. As a result, companies should be enabled to opt out of hedge fund activism by way of dual-class or at least loyalty shares, if a majority of institutional investors agrees to this solution ex-ante.

Introduction

Some ten years ago, a prominent law and economics commentator defined hedge funds (and private equity funds) “the newest big thing in corporate governance” (Macey 2008: 241). Activist hedge funds are definitely the big thing in corporate governance today. They intervene in corporate governance with the goal to make changes happen. So do private equity funds, but there are two differences. For one, hedge funds are supposed to unlock existing value, whereas private equity purports to create new value. Secondly, hedge funds confront the management of public companies, whereas private equity makes friendly deal with them to take the company private. This entry focuses on hedge fund activism as a disciplinary mechanism in the governance of public companies.

Although hedge fund activism has emerged as an US phenomenon, it has now become international (Becht et al. 2016). Hedge fund activism is increasingly prominent in Europe, for instance, in the UK. Moreover, hedge funds are active in

concentrated ownership structures, too. Somewhat surprisingly, activist hedge funds have succeeded in extracting concessions also in the presence of dominant shareholders. Importantly, hedge funds do not always achieve outcomes from engaging the management and do not need to engage overtly in order to achieve outcomes.

Activist hedge funds screen the market for underperforming companies and buy a significant stake in them in order to engage their management. The goal of activists is to make a profit from improving the company's performance, which will be reflected by an increase in the value of their stake when it is sold back to the market. In doing so, hedge funds are coping with the fundamental agency problem stemming from separation of ownership and control, namely, the failure by management to maximize shareholder value. However, because hedge funds profit from a short-term change in the stock price of the target company, they may also be responsible for short termism in corporate governance. Feeling the pressure of hedge funds, managers may pursue short-term stock returns at the expenses of long-term value creation. For this reason, hedge fund activism is highly controversial.

From a law and economics standpoint, the question is whether hedge fund activism remedies or exacerbates market failure. On the one hand, the reduction of agency costs stemming from activism improves the efficiency of corporate governance. On the other hand, if the profitability of hedge funds activism depends on short-term pricing, the ability of corporate governance to sustain certain long-term projects may be undermined. To answer these questions, it is crucial to understand what drives hedge fund activism as well as the factors affecting its success.

Hedge Fund Business Model

Shareholder activism is not new. Activists, such as individuals or public pension funds, have always been prompting managers to act on some issue, sometimes for ideological reasons. Before the advent of hedge funds, however, such activism has not been very effective in achieving outcomes

of sort, let alone in affecting stock prices (Bratton and Mc Cahery 2015).

Hedge fund activism is different. Like other activists, hedge funds take actions aimed to change the way a public company is managed, without trying to gain control (Gillan and Starks 2007). However, differently from traditional activism, hedge funds strive to profit from the changes they provoke. This is called "entrepreneurial activism" (Klein and Zur 2009). The changes can be quite radical, such as the departure of the CEO or some other executives, if not the restructuring of the company. Likewise, activist hedge funds may seek to stop a change wanted by the management, for instance an acquisition.

The mark of entrepreneurial activism's success is whether the desired change happens or not. Hedge funds have a different business model than other institutional investors. Hedge fund managers charge a performance fee in addition to a percentage of the asset under management. The remuneration usually follows the so-called 2-20 rule: 2% of the asset under management plus 20% of any increase in the value of the portfolio. This remuneration structure aligns the hedge fund incentives with investors having a relatively high appetite for risk. Hedge funds profit from investing in stock that they can buy, hold, and resell at a higher price.

Two factors are key for the success of entrepreneurial activism. First, the hedge fund needs to be able to buy the bulk of its stake in the company, while the stock market does not anticipate the engagement. The moment the engagement is revealed, investors will anticipate gains, and discounting those for the probability that the engagement fails, the stock price will rise disabling further profit from activism. Second, the activist needs to be able to persuade the management to implement the desired changes. To increase its leverage with the management, the activist can use several techniques, ranging from news campaigns to threatening a lawsuit. The last resort, however, is a shareholder vote. Reached that point, the success of the engagement will depend on whether the activist has managed to attract sufficient support from other shareholders to get a favorable vote. This explains the

importance of proxy contests for activism in the USA and of the rules for initiating and executing a shareholder vote in the European jurisdictions.

The support by institutional investors is crucial for successful engagement. The typical hedge fund stake in the target company is slightly above 6%, which is not nearly a controlling one. As a result, activists must persuade other investors to vote for them. Similarly, engagement may succeed based on the sheer threat of winning a contested vote. From the moment the hedge funds formulate their demands to the management, both parties start to speak with the largest institutional investors, while the investing public is in the dark about the engagement. Management will give in to the activists' demands when it is clear they are going to lose the vote, whereas hedge funds will withdraw from engagement when they realize that not enough institutional investors will vote for them. The fight becomes public only when the outcome is ambiguous. Consequently, a substantial portion of hedge fund engagement takes place behind closed door. This is consistent with the theoretical literature on litigation vs. settlement, as noted by Bebchuk et al. (2017a).

As explained by Gilson and Gordon (2013), the tremendous influence activists have gained in corporate governance depends on the reconcentration of ownership occurred in the past few decades. The bulk of equity investment is no longer in the hands of dispersed individual stockholders, but is managed by institutional investors. In 2016, institutional investors collectively held 63% of US public equities. Institutional ownership is also concentrated. The largest five and 20 institutional investors control, respectively, above 20% and 30% (on average) of the voting rights in the 20 largest US public companies (Bebchuk et al. 2017b). This is very important for activists, who need to be able to speak rapidly with the people casting a majority of the votes. The situation is similar in Europe. A recent OECD study reveals that institutional investors own nearly 90% of UK listed equities (Isaksson and Celik 2013). Although the style of engagement differs considerably across countries, hedge funds activism consistently gets traction wherever institutional ownership is concentrated.

Although institutional investors are crucial for the success of hedge fund activism, they do not act as activist themselves. The reason is agency costs. Institutional investors are prohibited from charging performance fees. Instead, they charge fees as a proportion of the assets under management, which is for them the key variable to maximize. Differently from hedge funds, institutional investors care about relative, not absolute performance. Asset managers do not have incentives to monitor individual companies because competitors will free ride on their efforts. Therefore, the activists' teaming up with institutional investors seems to be beneficial for corporate governance. On the one hand, activists lower the agency costs of institutional ownership. On the other hand, institutional investors screen the activists' proposals and should sanction only the value-increasing ones.

Reducing agency costs undoubtedly improves the efficiency of corporate governance. However, this does not imply that hedge fund activism is always value increasing. Several objections have been raised concerning the judgment of institutional investors.

Critique of Hedge Fund Activism

A first point of criticism is that institutional investors may fail to exercise judgment in the presence of hedge fund engagement. Rather, they would blindly follow the recommendations of proxy advisors, notably including global market leaders such as Institutional Shareholders Services (ISS) and Glass-Lewis, to decide whether to vote for or against hedge funds. The incentives of proxy advisors to get corporate governance right are even more questionable than those of institutional investors, if only because advisors do not have stakes in the companies for which they recommend a vote. Nevertheless, US legislation has effectively encouraged institutional investors to purchase proxy advisory services to meet the obligation to disclose their voting and avoid embarrassment (Rock 2015). The European Union is now following suit (Pacces 2017).

Empirical research suggests that the impact of proxy advisors on the voting by institutional

investors may be not as decisive as it looks. To begin with, only the smaller institutional investors systematically follow the proxy advisors. Large asset managers, such as Blackrock, Vanguard, or State Street, seem to vote independently. Moreover, every study of proxy advisors' impact faces a fundamental reverse causality problem. In the end, although there are clear synergies in judgment (McCahery et al. 2016), it is impossible to determine how much proxy advisors influence large institutional investors and how much they are influenced by them. Although there are no specific studies on the impact of proxy advisors on hedge funds activism, a US study of uncontested elections reveals that ISS advice against the management shifts at most 10% of votes.

Another fundamental critique levered at hedge funds is that they may succeed without any screening by institutional investors, if they act as a coalition, namely as a so-called "wolf pack." Empirically, wolf packs account for about 22% of the engagements observed internationally and are associated with a higher success rate than individual engagements – 78% as opposed to 46% (Becht et al. 2016). On this basis, Coffee and Palia (2016) have argued that wolf packs are a nearly riskless strategy for hedge funds, suggesting that this may lead to over-engagement. However, the impact of wolf packs seems to be overestimated. Firstly, in more than one-fifth of observed wolf pack engagements, the engagement has been unsuccessful. Because unsuccessful engagements result in losses, even wolf packs face risks. Second, wolf packs are never large enough to control a majority of the votes, which makes institutional investors still decisive. Finally and most importantly, 78% of the overt engagements mapped internationally are not wolf packs. This cannot be random because hedge funds choose their battles. If they decide to join and form a wolf pack only when success is more likely, the success rate of wolf packs is overestimated.

The recurrent objection to hedge funds activism is short-termism. This critique is more difficult to handle because short-termism means different things to different people. In one respect,

this critique is not borne out by the empirical evidence. Both in the USA and internationally, the announcement of hedge fund engagement leads, on average, to a significant increase of the stock price. This increase is not reversed for up until 5 years down the road (Bebchuk et al. 2015), provided that the engagement is effective in determining change (Becht et al. 2016). Therefore, hedge funds are not short-termist in the conventional sense of "cutting and running." While useful to defend hedge fund activism from an easy rhetoric against them, this result says nothing about whether the stock markets is myopic relative to some horizon longer than the activists' holding period (1.7 years on average), let alone whether it makes sense to consider such a longer horizon to assess the performance of any particular company.

Theory and Evidence on Hedge Fund Activism

Underlying the short-termism discussion, there is a fundamental question about the desirability of hedge fund activism. Hedge fund activism is an important feedback mechanism in corporate governance, but its efficiency is not obvious. Assuming that other stakeholders either protect themselves by contract or are protected from externalities by efficient regulation (Pacces 2012), efficient corporate governance requires maximization of shareholder value. If financial markets were informationally efficient, there would be no difference between short-term and long-term maximization of shareholder value because any asymmetry would be arbitrated away. If, however, stock markets overweight the short-term profits of a company relative to its long-term profits, albeit temporarily, there is market failure. This is a problem for corporate governance to the extent that short-termism leads managers to make value-destroying choices. Whether this is actually the case is uncertain, though, as the management may more or less intentionally err towards the long term to justify underperformance (long-termism). Defining short- and long-termism is conceptually difficult

in the absence of a consensus on what constitutes the “right term” to maximize profit.

What is “right” term depends on the “right” strategy to maximize profit; both are difficult to identify. Stock markets are an impressive source of information in this respect, but alas, they are imperfect. Because they overreact to news, mis-price risks, and are prone to asset bubbles, stock market prices do temporarily fail to incorporate the value of future profit opportunities. When this is the case, the Efficient Capital Market Hypothesis (ECMH) does not hold true. Therefore, there may be a conflict between the pursuit of short-term results, which are immediately impounded in market prices, and long-term projects, whose expected results are underweighted or even overlooked by stock prices. Because the hedge fund business model is based on stock market prices, pressure from activist hedge funds may well turn the short-termism of stock market into short-termism of managerial choice.

The question whether public companies should be managed for a shorter or a longer term cannot be answered empirically. Data reveal that successful activism, on average, is associated with a stock price increase. However, this result is uninformative because hedge fund activism produces unobservable effects, too, and because the companies for which we observe engagements cannot be meaningfully compared to those that are not engaged.

The first part of the problem is that we only observe a portion of the true activism, the overt part, whereas a great deal of activism takes places behind closed doors. Moreover, the distribution between overt and covert activism is not random. Better-managed companies react in anticipation of hedge fund engagement, whenever this is a credible threat. Activists, on the other hand, may have to make their campaign public precisely when the targeted is more mismanaged, which overestimates the observable returns from engagement.

The second part of the problem is that companies that are or can be targeted by activists fundamentally differ from those that are not and cannot be targeted. The fact that companies successfully engaged outperform a market index, on average,

does not really show that activism improves performance. It only shows that target companies were undervalued relative to a market benchmark and that activism brings performance back in line with that benchmark. These studies cannot rule out the possibility that a target company would outperform the benchmark by a larger extent, if not engaged, because this counterfactual company does not exist and, if it existed, it would be a different firm. This fallacy affects as well the studies arguing that hedge fund activism is value decreasing on the grounds that comparable companies, which have not been engaged, outperform engaged companies in the long run (Cremers et al. 2016).

In theory, whether hedge fund activism is efficient depends on context. Some companies benefit from the correction of underperformance fostered by activist hedge funds, particularly in the presence of investor expropriation or misuse of free cash. For other companies, though, underperformance is temporary and the change of strategy promoted by hedge funds can indeed destroy value. The disagreement on the proper length of time in which to assess performance reflect a more fundamental conflict between two views of the target firm, one by the activist hedge fund and the other by the incumbent management. These views normally differ on strategic issues, such as whether the company should be leaner, more focused on certain businesses and cost-effective in carrying them out, which hedge funds typically like to see perhaps because they are impatient to cash in the profit from engagement. The opposite view that the company should pursue longer-term goals, typically fostered by the management, is equally legitimate although it may procrastinate the acknowledgment of mistakes or conceal the extraction of private benefits of control. For this reason, hedge fund activism should be framed as a conflict of entrepreneurship (Pacces 2016).

Who Decides on Hedge Fund Activism

Framing hedge fund activism as a conflict of entrepreneurship brings up the question who

decides on the conflict and whether this is efficient. As explained before, hedge funds need to garner institutional investors' support in order to succeed. Institutional investors, however, differ considerably from each other in terms of investment strategy and incentives. Their propensity to exercise voice to support or to stop hedge funds likewise differs.

Based on Bushee (1988), institutional investors can be broadly characterized as transient (small stakes, high turnover), dedicated (large stakes, low turnover), and quasi-indexers (small stakes, low turnover). According to Hirschman (1970), a fundamental activator of voice is loyalty, that is, a commitment not to exit. Transient and dedicated investors are not loyal. The former enter or exit whenever there is a tiny profit to make, as is the presence of hedge fund engagements. The latter compete with hedge funds on entering and exiting portfolio companies timely. Only quasi-indexers, exemplified by index funds, are loyal in Hirschman's sense.

Index funds are likely to be the decisive institutional investors in a hedge fund campaign. They cannot exit an investment they are dissatisfied with, so long as this investment is part of the index they track. Thus, they are committed to exercising voice. Empirical evidence seems to confirm this. Ownership by index funds in the USA increases the frequency and the success rate of hedge fund engagements requiring high voting support to succeed (Appel et al. 2016). Apart from this, however, very little is known about how index funds vote or are expected to vote on a hedge fund campaign. Assuming that index funds are indeed pivotal, whether they are the right arbiters between the opposing views of hedge funds and incumbent managers depends on context.

To illustrate the conflict of entrepreneurship with an example, a strategic issue on which the views of activists and incumbent management typically collide is quality and quantity of R&D expenditures. Activist hedge funds want companies to focus on developing specific products, which usually results in cuts of R&D expenditures and larger short-term profits. The managers usually ask for the return on R&D expenditures to be

assessed over a longer horizon. Reducing R&D expenditures does not necessarily imply that a company is less innovative. There is evidence that activism increases R&D productivity and output. Hedge fund activism, however, systematically reduces R&D input. This may be not the right choice for a number of companies. In particular, nonlinear innovation with long lifecycles benefits from conglomerate structures in which R&D input is large and can be redirected internally from a project to another. Those are precisely the structures that activists seek to break up.

Drawing on their long-term commitment to index tracking, managers of large index funds, such as Blackrock and State Street, have recently made public statements to distance themselves from the short-termism of activist hedge funds. However, such statements must be taken with a grain of salt. Whereas regulation effectively compels index fund managers to vote, they do not have the right incentives to decide on firm strategy. Index fund managers cannot benefit from firm-specific monitoring because their competitors can free ride (Bebchuk et al. 2017b). In pursuing relative performance, index fund managers will rather choose low-cost voting policies that are generally appreciated by investors. That is to say, index funds may support a hedge fund's request to cut on R&D expenditures not because it is efficient, but because the target has poor corporate governance. Whether it is efficient for the particular company to engage in linear or nonlinear innovation is a more idiosyncratic question than an index fund manager can answer. And yet the choice whether to invest for the long term or focus on short-term should depend on firm-specific variables, such as the competitive environment and the length of the innovation cycle.

Relying on the judgment of index funds is efficient in other situations. Often, what prompts hedge fund activism is waste of resources. Because index funds are expected to vote in a standardized, predictable fashion on a hedge fund's memo showing waste, hedge fund activism protects investors by way of committing management to being efficient. Facing the threat of hedge funds teaming up with institutional investors, managers have to be more careful about misusing

fee cash or being unresponsive to the competitive environment. In this perspective, hedge funds activism is a tremendous tool to stop management from being lazy or building empires.

In conclusion, index funds cannot always be trusted to screen hedge fund activism because they do not have incentives to make an informed decision on individual company's strategy. Nevertheless, the incentives of index funds are aligned with the interest of the investing public regarding the control of agency costs. Therefore, the problem whether a company should be exposed to hedge funds activism does not warrant a one-size-fits-all solution. Different companies may need different degrees of exposure to activism at different points in time. As a result, individual companies should be able to choose the exposure of management to the scrutiny by hedge funds and to alter this choice over time.

Policies Towards Hedge Fund Activism

Similarly to hostile takeovers, hedge fund activism is a disciplinary mechanism in corporate governance. If anything, activism is more effective than hostile takeovers to keep managers on their toes because it is cheaper to operate. Unsurprisingly, hedge fund activism has attracted as much criticism as hostile takeovers used to do, if not more. As a result, a number of one-size-fits-all policies have been proposed to fend off hedge fund activism.

The business model of activist hedge funds is based on the purchase of a "toehold" of undervalued stock to secure a reward for screening the market for potential targets. If target identification were revealed before the engagement, other investors would free ride on hedge funds' investment and reduce, if not eliminate, their reward. Free-riding is a mechanism that fundamentally undermines hedge fund activism, as it undermines hostile takeovers for comparable reasons. By nurturing free riding, the regulation of ownership disclosure and shareholder identification curbs hedge fund activism across the board.

The purpose of ownership disclosure is to reveal the build-up of significant stakes in a

company. This is important information for the investing public and the company's management. Regulation mandates transparency of large ownership on both sides of the Atlantic. The specific rules, however, differ between the USA and the EU. In the USA, ownership disclosure is triggered by the crossing of a 5% beneficial ownership threshold, after which the shareholder has 10 days to disclose its stake. These rules are sufficiently lenient to make the USA one of the legal environments most favorable to hedge fund activism. Although EU regulation also mandates a 5% beneficial ownership threshold, the time window to disclose it is shorter (4 days), and more important, these are only minimum requirements. The EU member states can and do set lower thresholds and shorter time windows, for instance in the UK, Italy, and the Netherlands. These stricter rules make hedge fund activism less profitable and thus less likely to happen.

In the USA, attempts have been made to curb hedge fund activism through stricter rules on ownership disclosure. Antiactivist legislation is well illustrated by the so-called Brokaw Act, proposed in 2016 by Senators Bernie Sanders and Elizabeth Warren (Brav et al. 2016). This proposed legislation took on board several previous anti-activist proposals (Coffee and Palia 2016). In the Brokaw Act, the most important curbs to hedge fund activism are: (a) shortening the disclosure period from ten to two days and (b) conferring upon the Securities Exchange Commission (SEC) the authority to determine when a group of hedge fund acted as wolf pack, and to mandate disclosure accordingly. The Brokaw Act has not become law at the time of writing.

In the EU, curbs on hedge fund activism have been adopted not by altering the regulation of ownership disclosure, but by introducing EU-wide shareholder identification obligations (Pacces 2017). Different jurisdictions have different rules on shareholder identification. In the USA, institutional investors can opt out of identification altogether. The EU rules, instead, seek to harmonize shareholder identification rules by requiring that all shareholders above 0.5% be identified by the company's management and the investing public. Differently from ownership

disclosure, the purpose of shareholder identification is to facilitate coordination between non-controlling shareholders. Whereas this policy seems consistent with encouraging the engagement of institutional investors, which is a goal of the EU, the cost of shareholder identification for corporate governance may be higher than the benefits (Enriques et al. 2010). Particularly the cost for hedge fund activism can be substantial, unless hedge funds manage to circumvent identification and purchase several toeholds without crossing the 0.5% threshold.

Ownership disclosure and shareholder identification are two examples of regulation curbing hedge fund activism across the board. As argued before, such one-size-fits-all curbs are inefficient. Law should enable individual companies to tailor exposure to activism to their circumstances, for instance, depending on whether is optimal for them to profile on short-term or longer-term strategies.

In several jurisdictions, companies can effectively opt out of hedge fund activism through dual-class shares, which are interesting relative to other antiactivist tools (such as low-trigger poison pills) because they commit some of the controller's own wealth to the claim that a project must be evaluated in the long term. The problem is that dual class-shares can only be introduced before the company has gone public, unless they are presented as loyalty shares. Formally, loyalty shares provide super-voting rights to any owner that retains the shares for long enough – say, 2 years. Practically, however, loyalty shares are only interesting for controlling owners, because institutional investors are reluctant to give up the higher liquidity of common stock regardless of the average length of their investment horizon.

Both dual-class and loyalty shares confer upon the controlling management super-voting rights. A founder concerned with the adverse impact of activism on certain styles of innovation can go public with dual-class shares, as for instance, Google did. In already listed companies, however, the management cannot exchange existing shares for two classes of shares, one with higher voting rights for the controlling group and one with lower voting rights for the investors. Such dual-class recapitalizations are prohibited. Loyalty shares

are a way out of this prohibition. Companies can issue them after having gone public because, formally, loyalty shares do not discriminate between shareholders. European legislation, for example in France, has sometimes gone as far as to allow the introduction of loyalty shares even despite the opposition of a majority of institutional investors.

Loyalty shares are a good instrument for individual companies to tailor exposure to hedge fund activism. However, managers could abuse their power to introduce them. It would be more efficient to allow dual-class recapitalizations explicitly and subject them to a veto by institutional investors. The ex-ante approval of such transactions by a Majority of Minority shareholders (MOM) is a good regime to support contracting between management and shareholders in the midstream. If a MOM vote is required to introduce dual-class shares, the management will have to persuade institutional investors that insulating the company from hedge fund activism, perhaps for a limited time, is value increasing.

Conclusion and Future Research

This entry discusses the role of hedge fund activism in corporate governance. Activist hedge funds are an important source of feedback in corporate governance. However, their influence is not always efficient. Although other institutional investors are decisive on a hedge fund campaign, their judgment cannot always be trusted. In particular, index funds appear to be most often decisive on a hedge fund campaign. However, they do not have the right incentives to decide on company's strategy. On the contrary, the optimal decision whether a company should be managed for the short or the long term depends on the circumstances faced by the individual company. Therefore, individual companies should be able to tailor exposure to hedge fund activism to their needs and to alter this choice over time.

We still do not know enough about hedge fund activism, because most part of it happens behind closed doors. In order for companies and legislatures to fine-tune the rules on hedge fund activism, it would be useful to know more about how

institutional shareholders actually vote and whether different categories of institutional investors are decisive on different campaigns. Moreover, it would be good to know more about the role of coalitions in determining success of hedge fund activism. These are interesting topics for future research.

Abstract

In this entry, we would like to show that Robert Heilbroner was not only the author of the famous best seller, *The Worldly Philosophers*, first published in 1953. Actually, he was an active and innovative scholar investigating many subjects, from development to finance, learning constantly on Marx, Keynes, or Schumpeter, and crossing boundaries between many social sciences. However the very core of his project remains a general inquiry on the nature and evolution of capitalism. He could

be considered as a late representative of institutionalism and a brother in arm of economists like John Kenneth Galbraith, Gunnar Myrdal, or Allan Gruchy. It is in the context of this general inquiry on capitalism that Heilbroner presented his main contributions to law and economics.

Introduction

Robert Heilbroner is mainly recognized as the author of an economics best seller, *The Worldly Philosophers: The Lives, Times, and Ideas of the Great Economics Thinkers* (1953). It is very likely that this success partly masks his numerous other works, bearing especially on political economy, capitalism, socialism, or economic methodology.

Critical of the orientation taken by economic analysis post-*General Theory* for its historical and depoliticized nature, Heilbroner continued to argue for a situated and historical approach which takes account of the political, sociological, and moral dimensions of economic change. In this way, economic philosophers such as Adam Smith, David Ricardo, Karl Marx, Thorstein Veblen, Joseph Schumpeter, and John Maynard Keynes, all embraced economic, social, political, and psychological problematics.

Their analyses aimed simultaneously to understand and act, with the view of adapting and controlling the capitalism of their times. Therefore they were not reducible to technical dimensions or expert assessments as many contemporary economic works are. As the objectivity which those aimed for seems to him to be a vain quest, Heilbroner considers that all research supposes a “vision,” a notion borrowed from Joseph Schumpeter, who defines this as a “pre-analytic cognitive act” comprising political motivations, social stereotypes, value judgements, etc. (cited in Heilbroner 1993b, p. 89). This vision permeates the analysis for it is constitutive of all social thought, and also because it is a psychological, even an existential necessity. And as such it does not constitute “correctable weakness” (Heilbroner 1996, p. 47). Ideology leads to not recognizing the rôle played by this “vision.”

The object of economic study is not given; it is constructed and isolated from social reality. On this point, Heilbroner moves away from conventional economics which reduces its object to a method, a science of choices, so as to privilege a “substantive” definition, in the sense of Karl Polanyi. A definition takes account of institutional configurations and social interactions in the supply of resources to societies. Thus he considers that any economic system, capitalism today, or in the past traditional or planned economies, remains transitory, historically situated, and susceptible to undergoing future changes.

Biography

Heilbroner was born in 1919 in New York. While studying at the University of Harvard, he was influenced notably by Alvin Hansen, Paul Sweezy, and Joseph Schumpeter. But his predilection for economic philosophers and history was truly expressed some years later at the New School for Social Research at the side of his master Adolph Lowe (1883–1995) during a “fascinating seminar on Adam Smith” (Heilbroner 1953, p. 7). Heilbroner shared with Lowe little interest in contemporary economic analyses which treated the environment – social, cultural, political, etc. – as given, while the originality of most economists up to Keynes was precisely the proposal of a general and heuristic vision of the present and the future of the capitalist system, integrating into their analyses elements as important as politics, culture, and social questions.

Heilbroner attempted in turn to adopt this approach in his work and particularly in those bearing on capitalism, which constituted one of his preferred objects of study (see especially *The Nature and Logic of Capitalism* (1986), *Behind the Veil of Economics: Essays in the Worldly Philosophy* (1988) and *twenty-first Century Capitalism* (1993a)).

He was astonished at the almost complete disappearance in economic discourse of the notion of capitalism to the advantage of supposedly more neutral terminology such as “free market society.” Reduced to a simple technical study of

market functioning, contemporary economic work neglected the fundamental rôle of the state by evacuating the cultural values and social foundations upon which the capitalist economy rested. The analysis of institutions, involving collective representations and judicial rules as much as social organizations, constitutes an indispensable condition for understanding the *nature* and *logic* of capitalism. Conventional economics thus conveys a political and social “vision” directly inherited from capitalism which it refuses to admit. Economic reality is not identified with an unconscious emergent social order; the state and other institutions have participated and participate in its structuring. The great majority of economists do not recognize “the fundamentally social and political nature of all economies – that is, the core of political and social norms that provide the drive and the acquiescence without which no economic system, especially if marked by great inequalities, would long exist” (Heilbroner 1998, p. 4).

Innovative and Original Aspects

He borrowed from Marx the idea according to which accumulation of capital constitutes the driving force of capitalism but taking into consideration the psychological and psychoanalytic deciding factors that underlie this logic of acquisition. So, it is less conscious than unconscious motivations which explain acquisitive logic and “specifically the universal infantile need for affect and experience of frustrated aggression” (Heilbroner 1998, p. 37).

The principal motivation for the accumulation of capital should be sought beside the power and the prestige that it confers. It is about satisfying a need for domination anchored in childhood which in capitalism has no inhibition, contrary to noncapitalist societies which have succeeded in limiting it culturally. The search for profit plays an equivalent rôle to territorial conquest for military regimes or to increasing the number of the faithful for religions. Hierarchy, power, and domination are thus inseparable from the accumulation of capital. The analysis of individual choices which conventional economics is focused on is

incapable of giving an account of this ensemble of logic which can only be understood from a socio-political approach.

The markets which permit the allocation of resources and the coordination of economic activity constitute the institutional economic basis of capitalism. But taken in isolation following the model of contemporary economists, they are insufficient to qualify capitalism and notably cannot permit an understanding of the logic of acquisition.

Finally, the distinction between a public sector, place of power, and a private sector, in which market economic activity is deployed, represents a last central characteristic of the capitalist system. This distinction constitutes a historical particularity as economic activity relying on its own rules, autonomous from the rest of social activities, does not exist in noncapitalist societies. Neither do societies isolate the exercise of authority in a delimited sector. This separation is thus a source of liberties, as political dissidence can find in the economic sphere sources of expression that are inconceivable in noncapitalist societies.

However, far from being opposed, the two sectors are mutually dependent, as the accumulation of capital is not able to be achieved without the support of the state on the one hand and a prosperous economy is necessary for the financing of public activities on the other. The state even has a priority: supporting the accumulation of capital upon which depends its financial resources. Keynesianism and its inverse, the economics of the fight against inflation of the 1980s, have displayed how the capitalist system is now connected to and dependent upon the political order. The state intervenes in the economic field not to transform it or for ideological reasons but so as to secure its own future. Economic thought recognized, with Keynes, the state as an economic actor but always as a necessary interference and not as an integral part of the social capitalist order.

Identically, there is, in Heilbroner, a delegation of public functions to capitalist functions, in particular in the organization of work within the productive sphere. This is a case of an “unrecognized transfer of political power from the state into private hands” (Heilbroner 1985, p. 100). The opposition between public and

private, often presented as constitutive of capitalism, is thus brought back into cause since there is mutual interpenetration between the two sectors. Heilbroner undeniably here sees things from the perspective opened up by authors such as Karl Marx or Karl Polanyi for whom the state is a central actor of the institutionalization of the modern economy. The crises which have multiplied since the end of the nineteenth century have shown that the state can use the budgetary instrument to temporarily shore up the defects of the system. But it is firstly by the intermediary of law that the state favors the accumulation of capital. Citing Ellen Meiksins Wood, Heilbroner even considers that capitalism represents the ultimate “privatization” of politics “to the extent that functions formerly associated with coercive political power... are now firmly lodged in the private sphere” (cited in Heilbroner 1985, p. 100).

Assimilating capitalism to a uniquely private regime constitutes a gross error. The state, through socialization, by the protection and stimulation of certain economic activities, actively supports capital. Recurrent economic crises have given rise to necessary public interventions showing the adaptable and evolving character of the social capitalist order.

Impact and Legacy

The economic philosophers were perfectly aware of this interpenetration of the private and public sectors which constituted in their eyes an indispensable condition to the accumulation of capital of a stable social order. Heilbroner emphasizes that the economic philosophers always envisaged a “bounded future” for capitalism (the stationary state in David Ricardo, associationist socialism in John Stuart Mill, etc.) (Heilbroner 1985, p. 143). It was to prevent or delay these potentially dramatic episodes that they conceived such vast enquiries with economic dimensions but also with social and political and positive and normative aspects.

Abstract

Whenever agents choose A instead of B, B instead of C, and C instead of A, a logical contradiction arises. This contradiction – also known as a value anomaly – characterizes genuine choices. Some organizations and firms, but also legal systems, markets, or even the human brain can be regarded as complex systems that manage the value anomaly by operating with multiple mutually incompatible ordering principles. Such a management – as opposed to a mere elimination – of these mutually incompatible values allows these systems to better cope with uncertainty, and to benefit

from the recognition of complexity. One of the central implications of these heterarchical systems is that there is no single scale on which unequals can be compared and, consequently, that commensuration is an active process which involves friction and opportunities for entrepreneurship. We argue that in a world that naturally seems to be characterized by these value anomalies, heterarchical organizations and, in particular, heterarchy as a complex system of valuation might well be a good response.

Definition

Heterarchy is a complex adaptive system of governance, an order with more than one governing principle. Heterarchies include elements of hierarchies and networks, but in a number of important ways, heterarchies are different from both of these systems of governance. The model of heterarchical governance is like plate tectonics: mutually self-contained orders with unclear hierarchies among them.

Origins of the Concept: A Value Anomaly

The concept of heterarchy dates back to 1945 when Warren S. McCulloch, a neurophysiologist, presented a problem defined by a logical contradiction that is characteristic for any system (be it a group of neurons, an individual, or an organization) that chooses A instead of B, B instead of C, and C instead of A. This value anomaly is present in any system that has to make a choice between two or more potential acts that are incompatible (McCulloch 1945, 90; cf. Shackle 1979). Without the logical contradiction – without two or more potential acts that are incompatible – there is no space for a genuine choice based on disparate evaluation criteria. A decision ultimately relying on an algorithm, on an overarching metric, suffices.

Law and economics as a discipline has been defined by such a logical contradiction. The field has forever faced a tension between the internal

order of the market and the internal order of the law. One tendency, when faced with such a heterarchy of values, is to attempt to regulate or otherwise clear up the conflict by defining and applying a hierarchy of values. This approach has been adopted by scholars developing the economic analysis of law, which is aimed at demonstrating that law really is about efficiency (Posner 1973).

Hierarchies of Values, Commensuration, and Genuine Choice

Whether we like it or not, conflicting demands and contradicting values form integral parts of complex systems which cannot be reduced to a single ordering principle. What is right may be, sometimes at least, fundamentally at odds with what is efficient, and getting rid of the heterarchy of values might be the wrong approach to begin with. A growing number of social scientists have recognized that heterarchies actually have strengths of their own, which we often fail to appreciate. These scholars suggest that our brain (Bruni and Giorgi 2015), firms and organizations (Hedlund 1986, 1993; Hedlund et al. 1990; Girard and Stark 2003), constitutional legal systems (Joerges et al. 2004; Halberstam 2008), and systems of global governance (Baumann and Dingwerth 2015) are all examples of heterarchies and that the value anomaly which McCulloch identified is a feature that defines these systems, not a bug to be done away with. Heterarchy seems to be the natural state of the world, and heterarchical organizations (including the brain) might well be a response to that world.

In a heterarchy of values, different and often incompatible logics of what is valuable are at play. Yet, the difficult requirement to reconcile incompatible situational logics may be eliminated by transforming qualities into quantities, in other words, through commensuration. When an overarching value like efficiency, equality, or fairness is found, the choice is reduced to figuring out which option scores better on the value metric. Commensuration transforms the system with a heterarchy of values into one with a

hierarchy of values. In such a system, a genuine choice between incommensurables is not necessary, it is in fact ruled out. While commensuration seems to be a *sine qua non* for a rational choice, the acceptance of a hierarchy of values might have performative collateral effects – commensuration may transform the character of one’s decision-making effectively turning one’s passions from something boundless and elusive to something graspable and orderly (Nussbaum 1986). The danger of such a transformation is that when it happens, we “must see the beauty or value of bodies, souls, laws, institutions, and sciences, as all qualitatively homogeneous and intersubstitutable, differing only in quantity” (Nussbaum 1984, 68; cf. Mill 1863); when such a transformation happens in economics, we become convinced that the relation between any two desired things is always conceived of as a problem of making the right trade-off.

Heterarchy, Incommensurability, and the Exchange of Unequals

Claims about incommensurability are typically made where different modes of valuing overlap and conflict with one another (Espeland and Stevens 1998). This happens at the intersection of diverse systems of worth that sustain disparate mental models and justify conflicting institutions and situational logics. But while some kind of commensuration is necessary for markets to exist, making artifacts commensurable requires effort; no artifacts – be it persons, goods, and organizations – are essentially commensurable on their own (Dekker and Kuchař 2016).

When people trade they exchange artifacts which they value less for other ones they value more. Trade is thus an exchange of unequals but possibly also of competing principles or notions of worth (think, e.g., about the legal differences between goods and persons). If one artifact is to be traded for another in a market, conflicting principles of valuation have to be reconciled through commensuration. Legal scholars often treat this question as a formal matter, what is necessary is a system that turns possession into property. It

seems to be the case, however, that equally necessary, perhaps even a prerequisite for trade to happen in markets, is a social process that by way of commensuration legitimates trade. And indeed, market interactions are embedded in frameworks that make comparisons of unequals possible and that legitimate these comparisons. These institutional frameworks enable agents to negotiate between different modes of valuing that make up the heterarchy of values.

Entrepreneurship and Legitimation of Markets

The social process of commensuration requires entrepreneurial action because trade is not naturally legitimate. We highlight three points why this is so: First, as we have demonstrated elsewhere, some broader agreement on what an artifact is good for greatly facilitates trade and is required for its legitimacy (Dekker and Kuchař 2017). Such an agreement may emerge when the meaning of exchange is contested. Second, by introducing a good, a price tag is put on the object which makes it comparable with many other artifacts (within a circuit of commerce, cf. Kopytoff 1988). In some cases, this might be considered illegitimate, allowing us to explain the existence of separate circuits of commerce, rather than unified markets (or one big market). This happens when commensuration with (some subset of) other goods is contested. Third, the entire idea of monetary valuation might be resisted, because it devalues the “sacred.” How much does a seat in parliament cost? On the margin, how much freedom should we give up to make our markets “more competitive”? Artifacts like voting rights or justice may under some circumstances be considered as unique. When this happens, commensuration with money is contested. In such cases, a unified metric is lacking, and we face a genuine choice.

None of the abovementioned examples rely on strict commensuration in that the artifacts in question are 3 ft long or 5 ft high. But they rely on a commensuration in terms of moral categories. Within these different moral categories and

hence within different circuits of commerce, we will find different norms of ownership and different norms of exchange and redistribution that will lead to different forms of property and contract law on which well-functioning markets rest.

Applications of the Concept Across Disciplines

The idea of heterarchy has been applied in fields such as anthropology, political science and institutional economics, international political economy, organization theory, or sociology. For example, Carole Crumley, an anthropologist, defined heterarchy as “the relation of elements to one another when they are unranked or when they possess the potential for being ranked in a number of different ways” (Crumley 1995, 3). She found hierarchical theories to be inadequate in explaining the emergence of modern states. In her seminal paper, Crumley criticized the idea that order in human society must rest on hierarchical systems of governance mechanisms pointing toward a “conflation of hierarchy with order [that] makes it difficult to imagine, much less recognize and study, patterns of relations that are complex but not hierarchical” (Crumley 1995, 3).

That order and hierarchy do not necessarily come together is a prominent message throughout the work of Elinor Ostrom who suggested that a heterarchical organization of water supply in California (Ostrom 1965) or polycentric organizational structure of public safety provision (Ostrom and Parks 1973) may, in fact, be a good idea for public policy: “not a single case was found where a large centralized police department outperformed smaller departments serving similar neighborhoods” (Ostrom 2010, 644).

The concept of heterarchy has also influenced the study of international relations and sociology of law through the idea of legal pluralism. Legal pluralism may lead to conflicts, tensions, and boundary disputes which often result from collisions between plural discourses of contradictory legal regimes. These tensions present international actors with paradoxical demands. Paradoxical double-bind situations typically arise when

the social environment makes ambivalent or contradictory demands to which organizations must respond. The organizational response to these paradoxical situations tends to be neither contract nor hierarchy but hybrid networks (Hutter and Teubner 1993) that may allow for the transformation of external incompatibilities into internally manageable contradictions.

Heterarchies as Complex Systems of Valuation

Inconsistency and contradiction between institutional frameworks can bring about opportunities for innovation and change. On the other hand, the overlap between institutional orders that sustain different modes of valuation are also sites of fierce struggle between different situational logics that give rise to different standards of proper and permissible behavior. When institutional frameworks that sustain conflicting modes of valuation overlap, uncertainty arises. This uncertainty creates opportunities for proponents of alternative modes of valuation that legitimate certain applications of novel artifacts. In such a perspective, entrepreneurship is not seen as a property of individual proponents of particular modes of valuation. Rather, entrepreneurship is a property of a group that may or may not allow for a heterarchy of values (Stark 2009).

Heterarchies are complex adaptive systems precisely because they interweave a multiplicity of criteria according to which performance may be evaluated, esteemed, or appraised. These heterarchies of worth are organizational structures in which a given element may simultaneously be expressed in multiple overlapping networks that maintain separate situational logics and that constitute separate orders of worth (Stark 2017; cf. Boltanski and Thévenot 2006). Contending frameworks can themselves be a valuable organizational resource that fosters entrepreneurship by bringing about uncertainty. Consequently, entrepreneurship as a feature of an organizational structure consists in the ability to keep multiple evaluative principles in play and to exploit the resulting friction that arises as a result of their interplay. Entrepreneurship exploits indeterminacy

by keeping open diverse performance criteria rather than by fostering consensus about one set of rules that would apply to every element in the whole system.

Higher Education

Karsten Mause
Department of Political Science (IfPol),
University of Münster, Münster, Germany

Abstract

This entry discusses the role of the market, the state, and the law in the higher education (HE) sector from a law and economics perspective.

Definition

The term “higher education” (HE) is mainly used in three related contexts. First, it is used to denote the level to which individuals have pursued their educational careers. A person who finished high school and, thereafter, received a degree from a college, university, or another HE institution is someone who possesses an HE – compared to individuals with lower levels of formal education as measured by degrees or years of schooling. Second, as will be discussed below, some claim that HE institutions offer (potential) students HE as some kind of commodity. And third, social scientists consider HE as a subsector or subsystem of modern societies alongside other societal areas such as the economic and legal system.

The Market

It is often argued that HE is a commodity which is supplied by universities and other HE institutions and demanded by students in the HE marketplace. On closer inspection, however, this simple HE-as-commodity analogy is misleading and needs some clarification from an economic perspective. What HE institutions in fact provide are academic programs which contain goods and services (lectures, tutorials, course material, etc.) that students may use during their course of studies. Moreover, HE institutions award degrees which students receive after the successful completion of a degree program. Students normally have to work hard to pass the required examinations – however, there are also so-called diploma or degree mills that sell credentials that require little or no study (Grolleau et al. 2008). While selling “fake” degrees or doctorates is not necessarily illegal, whether a “degree” from an obscure “university” really pays for the respective “degree” holder in terms of labor market success, social prestige or in another respect is a different matter.

Another issue, which is frequently discussed under the keyword “grade inflation,” is that it is by no means clear that graduates holding excellent degrees (as measured by excellent grades)

awarded by more or less prestigious HE institutions are likewise excellent in terms of knowledge and skills (Popov and Bernhardt 2013). Moreover, given the vast amount of institutions sailing under the flag “college” or “university,” one has to take a careful and critical look at the curriculum a particular degree-granting institution is providing (Altbach 2001). In the labor market, potential employers therefore have to cope with the problem of asymmetric information in the sense that they have to find out whether graduates’ labor market signals are credible – and which knowledge and skills a particular graduate of a certain college or university really possesses (Rospigliosi et al. 2014). In the HE systems of many countries, however, institutions have evolved that may help (potential) students and employers to overcome their informational problems. For example, university rankings and guidebooks try to separate good from not-so-good program providers. Accreditation agencies check whether programs and their providers fulfill certain quality standards – and, if so, award a seal of approval. Governmental authorities evaluate the quality of HE institutions and programs and award the label “state recognized.” And the good or bad reputation of a program and its provider can be considered as a market-based institution providing quality information (McPherson and Winston 1993; Mause 2010).

While academic programs and degrees are supplied by public and private HE institutions in markets, these institutions do not directly provide the market good “education.” The latter is in the possession (more precisely, in the head) of an individual. And what students can do is use the educational services (lectures, seminars, mentoring, textbooks, etc.) contained in academic programs to expand their already existing personal stock of education. The fundamental distinction between HE and educational services offered by HE institutions is not just a wordplay but refers to the real-world issue that “not all ‘schooling’ is ‘education,’ and not all ‘education’ is ‘schooling.’ Many highly schooled people are uneducated, and many highly ‘educated’ people are unschooled” (Friedman and Friedman 1980, p. 187).

Following this conceptual differentiation, HE is not a commodity like cheese or wine which can be bought in a market, as it is sometimes claimed in public debate. By contrast, the “customers” of HE institutions are producers of their own education: i.e., students have to invest time and effort to educate themselves with the help of the HE institutions’ staff members and services. These institutions may create an excellent learning environment and offer a state-of-the-art curriculum; yet, whether and how students use the provided support is another issue. And students or external observers (e.g., parents, education experts, or politicians) that are dissatisfied with “bad” lectures, seminars, professors, and so on should reflect that successful “service provision” within an academic program to some extent requires the active participation of the particular “client” (Rothschild and White 1995). In other words, there are limits to what HE institutions can do to achieve that their students are really learning and enhancing their knowledge and skills.

The State

In many if not all countries, governmental authorities play a role in the HE marketplace as characterized above. Governments at different jurisdictional levels, for instance, may be providers of academic programs. In Germany, the USA, and many other countries, there are not only private HE institutions but also public universities which are state owned and publicly subsidized to some extent. A political rationale for such governmental intervention is that “the state” intends to safeguard that the HE sector produces a sufficient number of graduates in various fields of study; a highly qualified workforce is regarded as essential to ensure the wealth of a nation and its international competitiveness. From an economic perspective, the expectation that there will be a private “underdemand” (i.e., “too few” students and graduates) and/or private “undersupply” (“too few” program providers) in certain fields of study may be an economic argument to justify government intervention in the form of public ownership

and/or public funding of HE institutions. However, due to the difficulty to forecast the future, there is a danger that governmental efforts to avoid “underproduction” and to steer the *quantity* of graduates (e.g., public funding, information campaigns) may lead to “overproduction.” That is, a well-meaning government action to stimulate demand and supply in fields where a “shortage” of graduates is diagnosed may promote the production of large numbers of graduates who subsequently have problems finding a job to match their academic qualification (Freeman 1976; Büchel et al. 2003).

In addition to governmental efforts to steer the demand and supply of academic programs, the state may intervene in the HE marketplace by regulating the *price* students have to pay for attending these programs. For example, to politically enable citizens from all social strata to go to university, currently in Germany students at public HE institutions generally do not have to pay tuition fees. The state may also regulate the *quality* of academic programs. The government may, for instance, influence what is taught and how it is taught at “its” public HE institutions. Moreover, governmental authorities could, via mandatory evaluations, monitor what is going on at private HE institutions (quality of curricula, teaching staff, graduates, etc.) and intervene if deemed necessary. From an economic perspective, it should be mentioned that there are private governance mechanisms which may be a complement or – under certain conditions – even a substitute for a direct governmental quality regulation by public bureaucrats: private accreditation agencies, university rankings by reputable organizations and media, or an HE institution’s good or bad reputation may likewise help (potential) students to separate good from bad quality and to make informed choices (McPherson and Winston 1993; Mause 2010). Whether a public, private, or public-private quality regulation in a jurisdiction’s HE system is perceived as appropriate, in democratic societies, is decided by the political system.

Furthermore, the government may control the *market entry* of providers of academic programs. In Germany, for example, governmental authorities check whether an HE institution and its

programs fulfill certain quality standards. This form of mandatory licensing is practiced mainly for the purpose of quality assurance and “consumer protection.” From an economic perspective, however, it is by no means clear that spending public money for public bureaucrats who control market entry is necessary: because it can be expected that no potential student (or only a few) will enroll in a program whose provider is not able to credibly signal in some way (e.g., via a seal of quality awarded by a reputable accreditation agency, well-appointed buildings and rooms, hiring some renowned professors, etc.) that it will offer students a high-quality program, value for money, and a degree that is recognized in the labor market. In other words, private governance mechanisms under certain conditions may be a substitute for governmental market entry control (Mause 2008).

And the Law

In many societies “the law,” which again may be influenced by government action, plays an important role in facilitating exchange in the HE marketplace (Russo 2010, 2013). For example, in the USA, the UK, and other countries, students enter contractual relationships with HE institutions. Students dissatisfied with the contractually agreed services can appeal to a court in order to legally enforce their “student contract.” Such contracts can be interpreted as another form of consumer protection in the HE sector: by this means, “student-customers” are to some extent protected by contract law (Farrington and Palfreyman 2012; Kaplin and Lee 2014).

There are other settings where students do not sign an explicit contract. This is currently the case, for example, at public universities in Germany. In this particular case, however, students study under the umbrella of public and administrative law. If, for instance, a department deviates from what is stipulated in the official study and examination regulations, dissatisfied students can appeal to university’s internal bodies (e.g., examination office), to the Ministry of Education of the state in which the public university is located, or to an

administrative court. To conclude, there are not only governmental but also private governance and legal mechanisms that govern the HE marketplace. All these governance mechanisms are imperfect and have their respective limitations. The relative performance of these mechanisms can only be assessed by means of an in-depth comparative institutional analysis of real-world markets.

²Centre National de la Recherche Scientifique,
Paris, France

Abstract

This entry will provide insights into Albert Hirschman intellectual trajectory and major concepts. We will over the main steps of his academic career and his major contributions to several and multidisciplinary fields. On the issue of law and economics, the entry underlines his high preference for pragmatic institutions (voice and the political arts of participation and deliberation at different social scales) and his everlasting caution to organic institutions (exit and spontaneous market mechanisms). However, we also state that in some of his contributions, Hirschman tried to rehabilitate, in an original and balanced way, the benefit consequences of organic institutions on the issues of growth and especially development.

Biography

We can single out two main times in the work of Albert Hirschman (Adelman 2013; Ferraton and Frobert 2003; Meldolesi 1995). The first one is devoted to development economics, a domain he is considered to have pioneered. This period laid the foundations of his approach thanks to the publication of *The Strategy of Economic Development* (1958). In retrospect, Hirschman explained that in these works his ambition was to “celebrate” and “sing the epic adventure of

development, its challenge, drama and grandeur” (Hirschman 2015, XVI). Then, around 1970, he wrote more general and cross-disciplinary works around Economics, Political Science, Sociology, History, and other social sciences. It was in 1970 that *Exit, Voice and Loyalty* appeared, which was to be followed by other contributions now considered as classics, such as *The Passions and the Interests* (1977) and *The Rhetoric of Reaction* (1991).

Of course, a sense of continuity and even unity can easily be found between the two series of contributions. Many commentators, from Michael Piore to, in the present day, Jeremy Adelman or Dany Rodrik, have emphasized the special, personal dimension of Hirschman’s work. A dimension revealed by a capacity to invent notions which are at once disconcerting and enlightening – such as the *Principle of the Hiding Hand* or the *Blessing in Disguise* – by a constant effort allowing problems to be mapped out, and so to be solved, by the habit of working upon language and by combining the paths of literary and scientific enquiry, etc. Even if he always avoided offering universal methodological solutions, Hirschman nonetheless sketched out the tacit rules of his approach: possibilism. Resisting any positivism, he emphasized that his research was “pervaded by certain common feelings, beliefs, hopes, and convictions and by the desire to persuade and to proselytize which such emotions.” To clarify his credo, he adds “for the fundamental disposition of my writing has been to push back the limits of that which is or is perceived as possible, be that at the price of a weakening of our capability, real or supposed, to discern that which is probable”; and for to this purpose, to constantly “underline the multiplicity and creative disordered of the human adventure, to bring out the uniqueness of a certain occurrence, and to perceive an entirely new way of turning a historical corner” (Hirschman 1971, 26–27)

Fashioned in this way, the iconoclastic work of Hirschman is partly the result of a tumultuous life, the academic side of which began relatively late. Very early on, and notably in 1930s Germany, he was able to observe at first hand the apparent omnipresence of violence in human transactions,

the tendency of societies, including the most advanced, to be rotted away by an apparently inexorable process of brutalization. At the origin of this process, multiple processes of decline can be observed (for nations and civilizations), and of failure or falling activity (for organizations and businesses). How can warning be given and then action taken when decline or falling activity are displayed? Against all fatalism, Hirschman chooses to interest himself in the intrinsic capacity of adaptation of human communities, as well as in the conditions of its expression; whatever the scale of the measure, the action is possible and the discourse on the laws, the regularities, the instructions of history, nature or society should be nuanced.

His work constitutes a vast enquiry about principles but also about the craft that can favor the emergence, maintenance, or defense of a reasonable social, political, or economic environment. The question of action which is collective and turned towards reform is thus at the heart of his intention. This explains that he could consider since his first works on Latin America that “the fundamental problem of development consists in generating and energizing human action in a certain direction” (Hirschman 1958, 25), or that he concentrated his later thinking upon “the micro-foundations of a democratic society” and to the “constitution of a democratic personality” (Hirschman 1995).

Innovative and Original Aspects

This general orientation thus allows us to approach the question of law/economics in Hirschman. These relations depend on the new and singular fashion by which he treats the question of institutions. We are familiar with the opposition established by Carl Menger between “organic” institutions and “pragmatic” institutions (Menger 1883). “Pragmatic” institutions present themselves as rules and organizations resulting from collective, concerted, and planned action. They make concrete a design consciously developed by one or many individuals. However, organic institutions are the unintentional

consequence of intentional individual actions. Put in another way, an organic institution is a social consequence, unanticipated, even unwanted, which is the result of actions undertaken by many individuals independently of each other. Menger explains that numerous social phenomena spring from this process in terms of organic institutions: law, language, the market, and money are all institutions that are at least partly organic.

Within the framework of this alternative, the work of Hirschman swings very clearly to the side of pragmatic institutions. A key contribution such as *Exit, Voice and Loyalty* can thus be interpreted as a defense of the paths of economic, social, and political reform by the privileged means of pragmatic action. Opposing the teachings of *The Logic of Collective Action* by Mancur Olson, Hirschman emphasizes that the efficiency of the process, described by economists as simultaneously spontaneous, optimal and exclusive, that represents the market (*exit*) faced with the different risks of “slackening off” for institutions and organizations, should be questioned. Another process, more determined (*voice*) a characteristic of political action, should, at least be considered as complementary, and doubtless, most often, as a clearly preferable alternative. *Exit* appears thus as a secondary substitute.

Hirschman’s preferences concerning the two processes are in fact obvious: while *exit* is taxed as being a form of “desertion,” “*voice* is essentially an *art* constantly evolving in new directions” (Hirschman 1970, 43) and again a faculty of invention. He specifies elsewhere that the role of speaking out within an organization can be assimilated to the exercise of a democratic control founded upon the interaction of opinions and interests. In the context of the neoliberal movement of the 1980s and attacks made upon the welfare state, the tendency to favor the pragmatic over the organic will be evident in Hirschman, engagement in favor of public action becoming the supervisor in relation to an activity which is entirely turned towards private well-being (*Shifting Involvements* 1982). A little later *The Rhetoric of Reaction* studied, so as to reveal, the three rhetorical devices systematically mobilized

over the history of the two last centuries by conservative/reactionary opinion (perversity, futility, jeopardy) to stigmatize any determined attempt to improve the civil, political, and economic situation of the greatest number.

Nevertheless, as in all parts of his work, Hirschman tries to question his own opinions (his “propensity to self-subversion”) to establish dialogue with the adverse party to improve the conditions of the explanation. Thus, he explains that at the very heart of conservative tradition a concept of social change can be seen, as well as institutions which, correctly reformulated, can be included in the arsenal of the social reformer. In fact, notes Hirschman, the Hayekian paradigm of the unexpected consequences of action and the emergence of organic institutions has too clearly been monopolized, in his opinion, by conservative thought. However, this explanatory model of social change has virtues which would merit their being solicited by progressive/reformist thought.

Progressive/reformist thought, in fact most often mobilizes a model of social change that is too crude: a model stained by Prometheism and in which change intervenes as a mass, from above and according to sequences presented as entirely determinable and planifiable in advance; a model in which actions cannot, nor must not have unexpected consequences; a model in which also dominates as a consequence the expert, the money doctor and others, *deus ex machina* of a world that is entirely measurable.

However, from his first works on development, as he was confronted with the problem of generalized underemployment of existing but dormant resources which characterizes the least advanced countries, Hirschman asked for the use of a *strategic* approach. In that case, it is necessary, as in the case of the Keynesian multiplier, but to a greater degree of generality, to create an impulse, then let the fertile multiplying phenomena develop. And in this context, it is thus necessary to reflect in strategic terms, that is to say, in terms of actions of impulse at different levels, including and especially at intermediate levels, and at different moments to support much more than

fully control the chains of phenomena which will develop.

Hirschman thus explains that, in terms of models of change, a strange twinship can be suspected to exist between the Keynesian model centered on the multiplier and the Hayekian paradigm of action. Starting in *The Strategy*, Hirschman explains that “development planning” thus consists of putting “*inducement mechanisms*” systematically in place. Here there is a clear hope placed in the generalization of certain multiplying phenomena, an initial action leading to an unforeseen chain effect of positive consequences. But here the issue at stake becomes not to declare them, for cognitive reasons or other impotencies vis-a-vis these chains of phenomena, but to learn as much about them as possible so as to recognize them and watch over them. He took up this idea later: “it is possible to plan with success; to put it another way, we are not always surprised by unexpected consequences” (Hirschman 1997, 96).

Impact and Legacy

Originally marked by the experience of totalitarianism, then by field and conceptual work, in the domain of development, and finally by thinking upon the ensemble of history and the social sciences, Hirschman thus presents a complex conception of institutions and the articulation of economics/law. A concept which proceeds from the emergence and the evolution of economic phenomena – here also should be mentioned his micro-Marxism – and which brought his attention to the multiple possibilities which, collectively, offer themselves for the exploitation of their positive dimensions, thus to form obstacles to the incessant risks of decline and failure which menace human organizations and communities.

Horizontal Effects

Philipp Schumacher
Wildau Institute of Technology, Technical
University of Applied Science, Wildau,
Brandenburg, Germany

Definition

Horizontal effects are the anti-competitive consequences of mergers where the competitive constraints existing before the transaction between the merging parties are eliminated (unilateral or non-coordinated effects), and/or the post-merger market structure reduces the intensity of competition between the remaining competitors (pro-collusive or coordinated effects).

Horizontal Effects

Non-coordinated effects refer to a situation where, post-merger, the merging parties are able to

profitably increase prices, reduce output, or otherwise act less competitively than before, while their rivals do *not* alter their strategies. Non-coordinated effects arise from the independent profit maximization of the individual firms and are due to the internalization of competition between the merging firms. Before the merger, a unilateral price increase by one party would have led to sales lost to competing firms, including the other merging party. As a result of the merger, the parties can absorb some of the competitive pressures. The incentive to increase prices strongly depends on the closeness (or degree of substitutability) of, firstly, the merging firms' products and, secondly, the existence of close substitutes offered by non-merging firms. Consequently, one of the fundamental elements of the European Commission's Horizontal Guidelines is the assessment of the closeness of competition to forecast non-coordinated effects. In order to determine the cross-price elasticity of demand between several products, economic methodology is required for robust modeling and correct interpretation of the results.

In the Horizontal Guidelines, the EC recognizes that market share is not necessarily the best indicator of market power or non-coordinated effects in the sense of ability to raise prices, and it attempts to include additional economic aspects into the assessment, e.g., the probability of post-merger anticompetitive effects in the absence of any countervailing factors and the probability of buyer power, entry of new competitors or efficiencies as factors mitigating harmful effects on competition, as well as the conditions of a failing firm defense.

A merger is said to give rise to concerns regarding *coordinated effects* when the consequent change of the nature of competition better enables the merged firm and at least one of its competitors to reach and sustain a tacit agreement not to compete effectively with one another and thereby raise prices. A merger may also make coordination easier, more stable, or more effective for firms which were coordinating prior to the merger. Coordinated effects arise if, due to the merger, non-merging competitors change their

strategies, resulting in (or reinforcing previously existing) coordinated behavior, i.e., explicit or implicit collusion. Post-merger, it may be easier for the firms in the relevant market to imitate monopoly-type behavior by acting collectively. The coordination may take various forms, for example, keeping prices above the competitive level, limiting output or new capacity, dividing the market, or allocating contracts in bidding markets (European Commission 2004, para. 40; U.S. Department of Justice 2010, p. 24–29). The likelihood of such behavior is determined by how easy the establishment of coordination is in a given market and how sustainable it is over time, dependent, in particular, on the existence of a credible monitoring and punishment mechanism for deviations. The EC Guidelines require the commission to prove that such conditions exist in the respective market before claiming that sustained coordinated behavior is likely to occur.

According to the Guidelines, coordination is more likely to emerge in markets where it is relatively simple to reach a common understanding on the terms of coordination. Additionally, the following conditions are necessary for coordination to be sustainable:

- The firms in the coordinating group must be able to sustain any tacit understanding. This requires them to be able to monitor that the tacit understanding is being adhered to by the other firms.
- If a firm does deviate from the tacit understanding, the other firms must be able to respond effectively (i.e., retaliate) to penalize that firm.
- For the tacit understanding to be sustainable, it must be immune from the potentially destabilizing reactions of firms outside the coordinating group.

Horizontal Product Differentiation

Javier Elizalde

Department of Economics, University of Navarra, Pamplona, Navarra, Spain

Abstract

This essay provides a definition of horizontal product differentiation and a short description of its implications for Law and Economics, as the degree of product differentiation affects the degree of competition and therefore the level of prices. A short revision of the literature on horizontal product differentiation is performed.

The aim of the literature is to predict the number of varieties or the degree of differentiation (when the number of varieties is fixed) in an industry. Different works find different solutions to this problem.

Definition

Horizontal product differentiation takes place when, at a given price, some consumers prefer different varieties of the goods.

Horizontal Product Differentiation

A number of products are horizontally differentiated when, if they were all sold at the same price, all of them would be demanded by one or more consumers. The existence of horizontal product differentiation implies that the market cannot be described by perfect competition but firms enjoy some degree of market power as, if one of the firms increases its price, some consumers would switch to a competitor but some other consumers would keep loyal to their original supplier.

From the point of view of law and economics, the existence of horizontal product differentiation is relevant in order to identify the competitors for goods and therefore to define the relevant market. The degree of product differentiation determines the degree of market power, as the more similar the products, the more intense the price competition.

There are two alternative approaches to the analysis of competition with differentiated products. The first approach considered that all consumers had the same preferences for the different varieties of the goods, which were fixed (Bowley 1924). This analysis was modified by considering endogenous varieties and free entry, in what has been called in the literature the model of monopolistic competition (Chamberlin 1933). The second approach to the analysis of horizontal product differentiation is called the *address (or distance) approach* as it considers the degree of product differentiation as geographical distance between the different firms (Hotelling 1929).

Hotelling analyzed products which were differentiated in only one dimension (in his own example, he considered that cider could be simplified to be differentiated by the degree of sourness alone), and different consumers had different preferences for the different varieties of the goods. In the original Hotelling model, two firms entered simultaneously in a linear market and decided the product characteristic in the first stage and the price in the second stage. Any decision to change the product specification has a price effect and a market share effect: A firm has an incentive to offer a closer substitute to its rival's product in order to gain some of its customers, but this closeness implies a higher degree of price competition. The main goal of the address approach to horizontal product differentiation has been to define the equilibrium in the characteristics (or location) game, which represents the degree of product differentiation in the market. The prediction of Hotelling was that the two firms would be located in the center of the linear market implying minimum product differentiation. It was shown that the analysis of Hotelling failed when the firms were closely located as none of the price or market share approaches dominated the other (d'Aspremont et al. 1979).

The analysis of Hotelling was modified in order to get a perfect equilibrium in the two stages of the game. One of the assumptions that were modified was that the transportation costs of consumers are linear. By considering quadratic transportation costs, d'Aspremont, Gabszewicz, and Thisse solved the problem of nonexistence of equilibrium predicting maximum product differentiation. Other assumptions of the original work (primarily the existence of two firms, differentiation in a single dimension, simultaneous entry, and the fact that all consumers purchase one unit of the goods regardless of price) have been relaxed in recent works finding support for either maximum or intermediate degrees of product differentiation (Prescott and Visscher 1977; Salop 1979; Economides 1984, 1986; Irmen and Thisse 1998).

There are two noteworthy versions of the horizontal product differentiation analysis: The one that considered fixed prices and a fixed number of firms and looked for the location equilibrium for

each number of firms (Eaton and Lipsey 1975) and the circular market with an endogenous number of firms (Salop 1979).

Human Experimentation

Roberto Ippoliti

Department of Management, University of Turin, Turin, Italy

Scientific Promotion, Hospital of Alessandria – “SS. Antonio e Biagio e Cesare Arrigo”, Alessandria, Italy

Abstract

Human experimentations refer to medical investigations with humans involved as experimental subjects. These trials are prospective researches aimed at answering specific questions about biomedical interventions, generating safety and efficacy data on drugs and treatments, innovative devices or novel

vaccines, as well as new ways of using known interventions.

After a brief introduction of human experimentations, this section presents the main related issues in Law and Economics, i.e., the risk sharing between society and pharmaceutical industry.

Synonyms

Clinical trials; Medical experimentation

Definition

Human experimentation refers to a scientific investigation with humans involved as experimental subjects.

Clinical Research and its Organization

Human experimentations refer to medical investigations with humans involved as experimental subjects. These trials are prospective researches aimed at answering specific questions about biomedical interventions, generating safety and efficacy data on drugs and treatments, innovative devices or novel vaccines, as well as new ways of using known interventions. The investigation requires an ex-ante authorization by the competent Institutional Review Board (IRB), also called Ethic Committee in Europe, which is an independent authority designed to approve the experimental activity if an appropriate level of safety for the involved subjects is guaranteed.

According to a stylization elaborated by the US National Health Institute, the human experimentation can be classified as follows:

- Studies of phase I, researchers test an experimental treatment on a small group of healthy and voluntary subjects (20–80) in order to evaluate its safety, determine the dosage, and identify side effects.
- Studies of phase II, the experimental investigation is extended to a larger group of patients

(100–300) to see whether it is effective and further evaluate the safety.

- Studies of phase III, the experimentation involves 1,000–3,000 individuals and it is directed to gather a more extended dataset of information concerning its effectiveness of the treatment, side effects, the comparison with already existing treatments, and many other details.

The classification is based on the development stage of the innovative product and/or treatment. At earlier stages, investigators enroll volunteers and/or patients into small (pilot) studies and then, if positive safety and efficacy data are collected, they conduct progressively larger-scale studies. This is exactly the main risk of human experimentation, i.e., the possibility of collecting high level of toxicity and negative efficacy data, raising the main Law and Economics issue which is related to the human experimentation: the risk sharing between society and pharmaceutical industry (Ippoliti 2013).

Pharmaceutical Research and Development (R&D) is a complex of activities aimed at discovering and developing new products to care patients. Generally, the pharmaceutical R&D can

be stylized into two subsequent phases (Criscuolo 2005):

- The first stage, which is the basic research devoted to advance the current knowledge by designing new productive opportunities, i.e., new molecules, new compounds, or new techniques
- The second stage, which tries to make the previous discoveries workable by testing the innovative products on animals (i.e., preclinical test) and then on humans (i.e., clinical research or human experimentation)

The following figure summarizes the entire production process of the pharmaceutical company and, as it can be easily seen, the R&D process is the main productive activity with a deep economic investment. More precisely, clinical research is directed at collecting clinical evidence to obtain from the national regulatory agencies the authorization to market the innovative products. This step is mandatory in order to commercialize a drug and thus to make the investment profitable. However, as aforementioned, another opportunity to make the R&D activity easily profitable is risk sharing (Fig. 1).

Human Experimentation, Fig. 1 Production process of the pharmaceutical industry (Source: Les Entreprises du Médicament (LEEM Report 2008))

The sharing idea is linked to unexpected adverse events which companies and patients must face. According to Ippoliti (2013), in order to expand medical knowledge, not only does society need to accept companies' market power (monopoly) but also a part of the adverse risks linked to human experimentation. Only if patients accept to bear all expected adverse risks, signing the informed consent (The Association of the British Pharmaceutical Industry 1994), the opportunities to make the investment worthwhile will raise since the expected cost will decrease. The key role of this risk sharing is the informed consent, which might be viewed as a contract between research subjects and sponsor.

Imitation

Jen-Te Yao
Fu-Jen Catholic University, New Taipei City,
Taiwan

Abstract

Imitation is an idea adopted or derived from an original one and is a necessary tool for disseminating knowledge. The existence of imitation may lower the monetary returns of innovators and remove their creation incentives. This gives the rationale for the intellectual property right (IPR) protection system, whereby the returns of innovators can be secured and the incentives to innovate can be improved. The pertinence of such a viewpoint is, however, in doubt in some of innovative industries, such as software, computers, and semiconductors. Institutions that govern the creation and diffusion of inventions (knowledge) should balance the trade-off between IPR protection and imitating diffusion.

Introduction

Invention creates new knowledge, and a successful invention often leads to widespread imitation of other innovations. Imitation is an idea adopted or derived from an original one and is a necessary

tool for disseminating knowledge. Knowledge accumulation and innovation diffusion must be achieved via imitation. While invention is a discovery and proof of the workability from a new idea or method, innovation is the successful application of new inventions into marketable products.

Imitation is related to copying. Copying is an extreme case of imitation, because it is an exact reproduction of the original, such as a fake painting. Sometimes a fake painting can be so real looking that it is hard to tell the fake from the genuine article. One might recall a common proverb that “imitation is the sincerest form of flattery,” although artists and museum directors would probably disagree. An excellent invention may signal to imitators that opportunities are “good” and hence implicitly encouraging imitation. Without this signal, potential competitors might have no incentives to imitate.

When discussing imitation, we should understand the difference between imitation, counterfeiting, and piracy. Counterfeiting refers to the illegal copying of trademarks, patent or copyright infringement, where the protected rights to intellectual property are being violated. A counterfeit good is an unauthorized imitation of a branded good. Piracy is making an unauthorized exact copy – not a simple imitation – of an item covered by intellectual property rights (hereafter IPRs).

Imitation and the Incentives to Invent

Imitation as a factor in economic development has gradually received greater attention. A number of economists have examined the subject. They argued that firms imitating major inventions and diffusing them throughout the economy – not the original inventions themselves – play a critical role in economic growth. This is because complete technological progress consists of three stages: invention, imitation, and diffusion. In the last stage, diffusion is the process of the spreading of inventions through licensing, imitation of patented innovations, or adoption of unpatented innovations. Nobel Prize winner Jean Tirole emphasizes the importance of imitation and diffusion in economic progress. He notes that “Inventing new products is not sufficient for economic progress. The innovations must then be properly exploited and diffused through licensing, imitation, or simple adoption. The difference between imitation and adoption is that imitators must pay for reverse engineering – e.g., figuring out the original firm’s technology” (Tirole 1988). Therefore, an imitating work is not free, but rather has a cost.

Inventions and innovations require monetary returns to innovators in a market-based system. However, the existence of imitation may lower the returns and remove the creation incentives of innovators. This gives the rationale for the IPR protection system, whereby the returns of innovators can be secured. In general, stronger IPR protection raises imitation costs and reduces the number of imitators, which can be realized from the mechanism of patent protection. Patent protection has two dimensions: patent length protection and patent breadth protection. Nordhaus (1969) is the first to offer a model dealing with patent life or patent length, i.e., the number of years that the patent is in force and protected

from being copied. Nordhaus (1972) extends his model to study the effectiveness of patent breadth protection. Patent breadth indicates the extent to which a given patent covers the field to which it pertains. The breadth of a patent grant measures the degree of protection in the scope of a product’s characteristics. For example, if a company invents a new drug to alleviate a heart condition, to what degree can a competitor be allowed to sell a similar drug? If a computer software firm markets a new program, how different should rival products be from the original? One can conclude that if patents are narrow, then they are easy to “invent around”; that is, it is easy to produce a non-infringing substitute for the patented inventions. This constitutes a non-infringing imitation. An extremely narrow patent does not protect a product even against trivial changes, like color or size (Scotchmer 1991).

One can apply a spatial line to express this idea, as illustrated in Fig. 1. Suppose a firm invents a new product and obtains a patent grant. The breadth B of the patent is an exclusion zone in a technology space, whereby the patent holder has exclusive control over the application of the patented technology. The technology space is a closed interval due to the limitation of technology development. Now, a competitor enters the market and needs to consider where to locate its product characteristic legally in the technology space, in order to avoid infringement of the patent. For example, the competitor needs to employ engineers to conduct reverse engineering and to figure out the original firm’s technology. Such operations are costly. Imitation entry by a second firm causes the patented firm to compete in the given technology space. However, a broader patent protection leaves a smaller remaining technology space to potential competitors (imitators), making it more difficult for them to enter the

Imitation, Fig. 1 Non-infringing imitation in a technology space

market. One thus concludes that a broader patent leads to less entry and less competition. Consequently, the market price is driven to increase due to less competition, which hurts consumer surplus, but increases the original firm's profits. Imitation entry stops when the cost of imitation can no longer be covered by competition in the market.

Two implications are derived from the above discussion. First, a broader patent increases the original firm's profits due to less competition in the market, thereby improving the incentives of the original firm to engage in innovations. Second, an increase in patent breadth means a rise in imitators' entry cost. Such a view is supported by Gallini (1992). One can further infer that an increase in patent protection will reduce the phenomenon of imitation and thus reduce competition between firms in the market. On the other hand, if a patent is very narrow (and even in some cases where there is no patent protection) and imitation is sufficiently cheap, then firms will prefer to imitate rather than innovate. Under this situation a "waiting game" takes place (Katz and Shapiro 1987) – all firms wait for other firms' inventions to occur, and the result is in fact no innovations. See also Dasgupta (1988) for an early discussion and Choi (1998) who as part of a wider paper on patent litigation, patent strength, and imitation investigates the waiting game style behavior in imitation.

The pertinence of the above viewpoints is, however, much in doubt (Takalo 2001). Ever since the pioneering study by Mansfield (1961), researchers have reported evidence of the inability of patent protection to prevent imitation, with a few exceptions such as in the pharmaceutical industry. Bessen and Maskin (2009) observe an interesting phenomenon that some of the most innovative industries of the last 40 years – software, computers, and semiconductors – have historically had weak patent protection and have experienced rapid imitation of their products. Surveys of managers in semiconductor and computer firms typically report that patents only weakly protect innovation. Patents were rated weak at protecting the returns to innovation, far behind the protection gained from lead time and learning-curve

advantages (Levin et al. 1987). Patents in the electronics industries have been estimated to increase imitation costs by only 7% (Mansfield et al. 1981) or 7–15% (Levin et al. 1987).

Imitation and Social Welfare

The strength of IPR protection substantially affects the speed of imitation. The following question arises: Does a strengthening of IPR protection have economic benefits for the society? The empirical literature on innovation shows that "imitation" is a nontrivial exercise that (even in the absence of a patent) may require substantial time and effort (Dosi 1988). Increased protection of IPRs makes imitation more difficult, which generates a trade-off on the improvement of social welfare. On the consumer demand side, stricter IPR protection implies that there will be less price competition between firms, resulting in higher prices and thus a reduction of consumer surplus. However, on the supply side, stricter IPR protection reduces competition between firms, which creates greater returns for the existing innovators and provides incentives for them to innovate. Therefore, stricter IPR protection is bad for consumers' well-being, but is good for innovators' private returns: no one wants to invest in the creation of inventions if imitation cost is very low and dissemination of inventions occurs rapidly.

To summarize, from society's point of view, the welfare effects of imitation depend on the balance of two elements: one is to provide a means for the knowledge producer to capture the benefits of efforts put forth and the other is to maximize the social dissemination of the related inventions. Institutions that govern the creation and diffusion of inventions (knowledge) should balance this trade-off, and this is why it is important to devise social mechanisms to allow inventors to capture a fraction of the benefits generated by the inventions.

Immigration Law

Thomas Eger and Franziska Weber
Faculty of Law, Institute of Law and Economics,
University of Hamburg, Hamburg, Germany

Abstract

In this article we provide some insights into relevant law and economics research on immigration laws and policies. After discussing some typical motives of migrants, we deal with the most important welfare effects of immigration

and their distribution, and try to understand why nation states regulate immigration more restrictively than the mobility of goods and capital. We refer to the example of the free movement of EU citizens. Lastly, we present some economic insights into asylum law.

Definition

This contribution considers scholarly works on immigration law with a focus on law and economics insights into labor migration and refugee law.

Introduction

Immigration, i.e., the movement of people – usually for permanent residence – into another country or region to which they are not native, is in many respects regulated by the countries concerned. In the following, we discuss some typical motives of migrants ([why migrate?](#)), deal with the most important welfare effects of immigration and their distribution ([Some basic welfare effects of migration](#)), and try to understand why nation states regulate immigration more restrictively than the mobility of goods and capital and why international agreements on immigration are less frequent than those on trade and investment ([Why and how do modern states regulate immigration?](#)). In this chapter, we also discuss the free movement of people in the European Union as an example for a far-reaching cooperation in this field. Finally, we conclude this entry with some ideas on asylum law from an economic perspective ([Asylum laws](#)).

Why Migrate?

A fundamental line of research regarding immigration matters concerns individual's motives to migrate. Migration can be triggered by a variety of reasons. Labor migration is a common form; other migration is family based. Some migrants may be attracted by another state's social welfare system. Others expect benefits from committing crimes or terrorist attacks in the country of destination. Many people are forced to leave their

We wish to thank Jerg Gutmann, Peter Weise and Katharina Eisele for valuable comments and André Plaster for useful research assistance.

country of origin because of political or religious persecution or are even victims of human trafficking. Needless to say, migrants are often not purely motivated by one reason but by a number of inter-related reasons.

Early efforts to model the migration decision of workers did not take into account the details of the legal environment. They are based on the human-capital model by Sjaastad (1962), which makes the migration decision dependent on the discounted net revenues and the monetary and non-monetary cost of migration. More recent work puts emphasis on the complexity of migration costs (for details see, e.g., Trachtman 2009): They consist, for example, of the direct cost of changing residence, the burden of bureaucratic procedures, the utility loss from abandoning social contacts in the country of origin as well as the time and effort required to establish new contacts in the country of destination, the time and effort required to learn a new language if necessary and to adapt to a different culture, the additional cost of finding an appropriate school for the children, lower pensions for people who have changed their countries of residence during their economically active period more frequently, and so on. At the same time, the benefits may go beyond the remuneration for labor and extend to all kinds of social benefits such as children's allowances, housing subsidies, unemployment relief, social welfare, and free access to schools and universities.

Immigration law affects migration costs by determining who is allowed to enter the country for how long and what are the legal consequences and procedures when people are infringing the law. In a broader sense, immigration law also includes all legal rules that govern access of immigrants to employment, social benefits, and so on.

Some Basic Welfare Effects of Migration

Welfare Effects of Labor Migration

Let us start with a very simple model of the migration of workers. (An excellent presentation of the economic analysis of migrant workers

can be found in Borjas (2014). For a recent overview of the economic debate on international migration, see Hatton (2014). Be aware that labor markets are different from goods and capital markets since – different from goods and capital – labor power cannot be separated from the worker. See, e.g., Eger and Weise (1989) with further references.) We assume there are two countries, home country H and country of destination D, there is a given capital stock in each country, capital and goods are completely immobile between the countries, and labor is homogeneous and perfectly mobile between the countries.

Initially, the quantity of homogeneous labor is $O_H L_0$ in country H and $L_0 O_D$ in country D. The curves $VMPL_H$ and $VMPL_D$ represent the value of the marginal product of labor in countries H and D, respectively. With perfect competition on the labor market, the wage rate is equal to the value of the marginal product of labor in each country. Since in the initial situation the wage rate and the marginal product of labor are higher in country D, the reallocation of labor from H to D will produce a gain in allocative efficiency. If there were no migration costs and if migrant workers were induced exclusively by wage differentials, migration would stop only when wages (and the value of the marginal productivity of labor) are the same in both countries. Thus, the total factor income in the receiving country increases ($d + e + i + j$), while that in the sending country declines by a lower amount ($d + e$). The welfare gain for both countries together is $(i + j)$. With positive migration costs, the new equilibrium will be somewhere between L^* and L_0 .

Equilibrium on migration market

However, apart from the overall welfare gain, migration produces even in this simple model winners as well as losers. The winners are migrant labor, gaining $(e + j)$, remaining labor in H, gaining b , and capital owners in D, gaining $(g + i)$, whereas the losers are capital owners in H, losing $(b + e)$, and the existing labor in D, losing g .

Of course, the welfare analysis has to be modified when we relax our strong assumptions. When we allow for heterogeneous labor, it becomes less clear who the winners and losers are. For example, immigrants, who have skills that are complementary to the skill mix of the country of destination, are typically less likely to create losers in this country. On the other hand, the country of origin may suffer losses from emigrating labor force, which used to create positive externalities in that country (so-called brain drain, see, e.g., Sykes 1995; Trachtman 2009; Boeri et al. 2012; Sykes 2013a).

When we allow for inflexible labor markets and unemployment, with homogeneous labor, unemployment will increase in the country of destination and decrease in the country of origin. Without additional assumptions, it is not clear whether unemployment in both countries together will be increasing or decreasing. If immigrants have complementary skills to those of the labor force in the host country, unemployment may decrease in the country of destination (Brücker and Jahn 2011).

When we allow for the mobility of goods, we have to take into account that immigration does not only exert pressure on the wages in the host country but also changes its production and trade structure, for example, toward more labor-intensive production (Hanson and Slaughter 2002). Moreover, it should be mentioned that the mobility of labor is usually accompanied by mobility of capital in the same direction, which is due to the fact that immigration to a country with a fixed stock of capital increases the rate of return on capital (Ottaviano and Peri 2006).

Extending the Basic Model

The provision of labor cannot be looked at in isolation. Based on what we have set out in the previous section regarding individual's reasons to

migrate, we have to modify our simple migration model by getting rid of the assumption that migrants are exclusively motivated by differences in gross wages (corresponding to the values of the marginal products of labor). In a more realistic scenario, migrants will also take into account the costs and benefits of the welfare systems in the countries concerned. Actually, migrants will be induced by *differences in net compensation* in the broadest sense, i.e., gross wages minus all kinds of taxes and contributions to the welfare system plus all kinds of social benefits. In this case, part of the migration could be induced by redistributive motives instead of differences in productivity, with at least two possible negative consequences:

- First of all, *people may be induced to emigrate even though their marginal productivity (and their labor income) is lower in the country of destination than in the country of origin*, if the difference in wages is overcompensated by generous social benefits in the country of destination.
- Secondly, if workers with low skills and low income have strong incentives to migrate to countries with generous *social insurance systems*, these systems may *get under pressure* (Sinn 2003, p. 64).

It depends on the respective immigration law and its enforcement to what extent these consequences will arise. Interestingly, for long periods in history, human migration was not subject to any legal constraints (Trachtman 2009, p. 3). However, we can identify market failures that make legal intervention desirable.

Why and How do Modern States Regulate Immigration?

Preliminary Considerations

There is a strong argument from an allocative efficiency point of view to get rid of all restrictions on economic migration (Chang 1997; Trachtman 2009, p. 33; Sykes 2013a). Some scholars claim that there is, hence, no need for an immigration

policy whatsoever (Hayter 2000). It may be desirable to eliminate all immigration controls.

In order to justify a legal intervention, the economist looks for market failures. Looking at immigration generally, the prevalent view among scholars is that international migration can be accompanied by important nonpecuniary externalities (Sykes 2013a, p. 319). These include, by way of example, the additional burden on the welfare state (welfare migration) or may result from the congestion of certain public facilities, from migration which is motivated by higher returns to crime, the import of infectious diseases, and the possibility that migrants may through voting patterns redistribute resources to themselves. These are, hence, a number of varieties of externalities that require at least some border control but in many cases also some regulation of immigration. From a public choice perspective, there is a simple explanation for the existence of regulating the entry of immigrants. As we have shown in the previous chapter, there are winners and losers of immigration. If the losers are better organized than the winners, the former will lobby for a restrictive immigration policy.

The next question when assessing a legal intervention is the welfare standard one wants to apply. There are two main measures to assess immigration policies: One suggests the use of a global welfare function that weighs the welfare of all persons equally. The second trend focuses on national welfare functions in which only the effects on the host countries are considered, excluding the effects on the immigrants' welfare or the welfare of their home countries (Trebilcock 2003). When it comes to arranging for immigration policy at a global scale, hence, the insight that gains are not symmetrical for the countries makes the success of such efforts more unlikely (Sykes 2013b). Even if welfare may be increased at the international level, migration will lead to winners and losers in different countries but also within the countries. Evaluations, hence, depend upon whose welfare is being looked at.

Instruments of National Immigration Policy

Immigration policies in major destination countries, such as the United States, Canada, and

Australia, are characterized by a large degree of centralization (see for the following in detail Trebilcock 2003). State authorities conduct basic health, criminal record, and national security checks and rely on a quota system, which distinguishes between three primary classes of immigrants: independent applicants, family members, as well as refugees and asylum seekers. For each class and respective subclasses (e.g., workers with different skills), the states determine quotas limiting the number of respective immigrants. Moreover, the governments issue short-term visas for tourists, students, and temporary workers, who might become immigrants in the future. There are two major problems with this centralized approach of regulating immigration:

1. It is not guaranteed that only those applicants are excluded who are expected to create an unacceptable burden on the amenities of the welfare state. When competing for skilled migrants, burdensome procedures can be a large disadvantage. (With respect to the European Union, see Kocharov 2011.)
2. Since the quotas have to be set in advance, the centralized bureaucracy is confronted with the very difficult (if not impossible) task of predicting the future needs of the labor market.

A further question in this regard is the institutional design by which quotas should be implemented. The basic options are *ex ante* or *ex post* screening (Cox and Posner 2007). An *ex post* system evaluating post-entry conduct is said to provide more information and, hence, a more accurate screening than an *ex ante* system on the basis of pre-entry information. Overall, both have a number of strengths and weaknesses. A main concern with the *ex post* system is that immigrants live with the fear of deportation, an uncertainty, which may hamper their integration process to the detriment of the host country.

An alternative approach, which could avoid many of the problems regarding independent applicants and family members and which is to a large degree implemented in the European Union, relies on decentralized agreements between the parties concerned, such as between migrant

workers and employers. In the European Union, various regimes apply. Crucially, migrants' rights differ as to whether the migrant is a European national changing his place of residence from one European member state to another (see [International cooperation on migration](#)) or a so-called third-country national entering EU territory. The positions of the latter, furthermore, differ considerably depending on the country that they come from (Eisele 2014). The European Union's major goal is attracting highly skilled workers from non-European countries. (One policy instrument is the Council Directive 2009/50/EC of 25 May 2009 on the conditions of entry and residence of third-country nationals for the purposes of highly qualified employment ("Blue Card Directive").) Whereas the rights of EU nationals are generally aligned, newly acceding states to the European Union may face different types of immigration policies by the various EU member states during a transition period.

A more decentralized system is capable of discouraging irregular immigration. A decentralized system would induce welfare-enhancing and deter welfare-reducing migration, provided there are safeguards that undermine migrants' possibilities to externalize costs to the sending or the receiving country. With respect to the receiving country, the risk of negative externalities can be reduced by (still) centralized health, criminal record, and security checks as well as by a mandatory insurance which avoids that the immigrants become a burden to the welfare state (Trebilcock 2003, p. 296). It is suggested that opening the border would be desirable if at the same time countries made their social programs inaccessible to non-citizens (Sykes 1995). (In Germany, the Academic Advisory Board at the Federal Ministry of Finance made in 2001 the proposal of "delayed integration," i.e., immigrants should enjoy taxed financed social benefits for a transition period from their country of origin. See Sinn (2003, pp. 80–81).) With respect to the sending countries, the problem of "brain drain" may arise if skilled workers, who generate positive externalities in their countries of origin, emigrate. However, one has to take into account that there may be also benefits to the sending countries, such as

monetary remittances and positive externalities by those migrants, who improve their skills in the host country and return to the country of origin later on (Trebilcock 2003, p. 282; Boeri et al. 2012).

International Cooperation on Migration

There is no doubt that there are many more barriers to international migration than to international trade and investment. Whereas many barriers to trade have been removed by multilateral, regional, and bilateral agreements and foreign direct investment has been fostered by more than 3,000 bilateral investment treaties (BITs), a comparable degree of international cooperation with respect to migration is (still) missing (Hatton 2007; Trachtman 2009; Gordon 2010). What are the reasons for this mismatch?

There is broad consensus that there are considerable gains from freeing up international migration, even though the estimates differ a lot (Rodrik 2002; Hatton 2007, pp. 345–346). For three reasons, non-coordinated national immigration policies will deviate from the globally efficient policy and will typically lead to over-restrictive immigration policies (Sykes 2013a, p. 320): (1) *Terms-of-trade externalities*: A large receiving country, facing an upward-sloping curve of immigrant labor, may have an incentive to restrict immigration in order to lower the price for immigrant labor. As a consequence, foreign workers absorb some of the costs of the migration restriction. (2) *Enforcement externalities*: Sending countries may have no incentive to reveal information on individuals with contagious diseases, with a propensity to commit serious crimes, or with a poor employment record to the receiving countries, even though they have better access to this information. Without cooperation, all receiving countries face high enforcement cost and will respond with restrictive immigration rules. (3) *Externalities among receiving countries*: Since the immigration policy of one country affects the flow of immigrants to neighboring countries, uncoordinated immigration policy will lead to suboptimal results.

However, to induce international cooperation on immigration, it is not sufficient that gains from cooperation exist. Two other requirements have to

be met to induce cooperation in immigration policy: (1) Gains have to be distributed in a way that all cooperating countries or, more precisely, the relevant interest groups in these countries win and (2) cooperation must be self-enforcing, i.e., all parties should expect that deviations from the cooperative agreement will trigger sanctions by the others. Thus, one has to take into account potential obstacles to beneficial cooperation (Sykes 2013a, p. 327): (1) *The one-way problem*: Different from trade, where typically most countries are interested in exporting goods to and importing goods from the other countries, migration is typically a one-way-issue. People migrate from poor countries to rich countries. Thus, negotiating mutually beneficial agreements becomes more complex, since the parties concerned have to rely on “issue linkage,” i.e., in exchange for accepting immigrants from less developed countries, the developed countries have to be compensated in “another currency,” e.g., by granting their exporters or investors access to the markets in the less developed countries. (2) *Migration diversion*: In analogy to trade diversion, bilateral or regional agreements on immigration policy discriminate against immigrants from third countries, which may lower social welfare in the immigration countries. One could argue that migration diversion can be avoided if international cooperation adheres to an equivalent to the most-favored-nations obligations under GATT. However, since migration is not controlled by tariffs but by a variety of complex rules and regulations, this obligation would be much more difficult to enforce.

An Example of Far-Reaching Cooperation: The Free Movement of Persons in the European Union

The European concept of the internal market, as defined in the Treaty, is founded on the four fundamental freedoms: the free movement of goods, services, persons, and capital. The underlying idea is to overcome the fragmented goods and factor markets that used to be a characteristic element of Europe after World War II. The free movement of persons between the member states was originally restricted in several ways: (1) The right of free

movement was restricted to *nationals* of the member states. (2) The right of free movement was restricted to the *economically active population*, i.e., to workers, self-employed persons, as well as providers of services. (3) Free movement was interpreted as a *prohibition of (direct or indirect) discrimination on the grounds of nationality*. From the very beginning, the Treaty has included a number of explicit derogations from the free movement of persons (public policy, public security, and public health derogations) and a public service exception. In the last 50 years, this situation has been changed by secondary legislation, i.e., in particular directives and regulations and by clarifying judgments of the Court of Justice of the European Union: (1) The *link* between the right of free movement and *economic activity* has been *removed*, by granting this right also to tourists, students, and others. With the Treaty of Maastricht (1993), the decoupling of free movement from economic activity culminated in the recognition of the status of “citizen of the Union” for all nationals of the member states (now: Article 21 TFEU). (2) The right of free movement was extended to *family members who do not have the nationality of a member state*. (3) The prohibition of discrimination on the grounds of nationality was extended to a general *prohibition of obstacles* to the free movement of persons (Brücker and Eger 2012, p. 146).

The Citizens’ Rights Directive 2004/38 confirms and extends the right of free movement of European citizens in the following way:

- For *stays of less than 3 months*, the only requirement on Union citizens is that they possess a valid identity document or passport.
- The right of residence for *more than 3 months* remains *subject to certain conditions*: Applicants must be either engaged in an *economic activity* or they must have *sufficient resources and sickness insurance* to ensure that they do not become a burden on the social services of the host member state during their stay.
- *After a five-year period of uninterrupted legal residence*, Union citizens acquire the *right of permanent residence* in the host member state.

Even though the European Union has been removing obstacles to permanent migration between member states to an unprecedented extent, the level of internal migration in the European Union has been modest (see the numbers in Brücker and Eger 2012, p. 158). The reason is that the EU member states, in particular, the “old” 15 members before the accession of Eastern European countries starting in 2004, are characterized by relatively small differences in per capita income levels. On the other hand, language barriers and to some extent also cultural barriers determine migration costs that cannot be removed by legal reforms. But still, there is sufficient evidence that the removal of barriers to the free movement of persons triggered migration, which has contributed to a small but visible increase in the aggregate GDP in the entire European Union (Brücker et al. 2009). Finally, there is no evidence so far that the removal of impediments to the free movements of workers would have triggered a mass inflow of unskilled workers from the East to the West and would have led to the exploitation of the welfare state in the destination countries (Boeri and Monti 2009; Brücker et al. 2009).

Asylum Laws

A rather new field in the economic analysis of the law concerns asylum/refugee law. In order to grant asylum to an asylum seeker, it needs to be determined that he or she is in fact a refugee. The core international agreement in this regard is the 1951 Convention Relating to the Status of Refugees as modified by the 1967 UN Protocol. Importantly, it provides a general definition of “refugee” and stipulates in the so-called non-refoulement clause that a person cannot be forcibly returned to a territory where she may face the risk of persecution. Most countries (and all developed countries) are parties to this Convention. From an economic perspective, international cooperation in asylum matters can be viewed as an agreement among states to supply the global public good of refugee protection (Bubb et al. 2011). While the Convention sets some common ground,

national asylum laws also show differences. Lately, one of the key challenges faced by asylum policies is the need to distinguish between “real” refugees and economic migrants. In economic terms, states face the problem of asymmetric information when assessing an individual’s status. They have a screening problem. Gradually, some countries’ asylum policies have become stricter in an attempt to cope with the challenge of identifying the type of migrant. An economic effect of differing standards in various jurisdictions is that states with stricter policies regarding their admission criteria impose an externality on those countries that have more lenient policies. This, in fact, may induce all countries to raise their standards – a “race to the bottom” (Bubb et al. 2011; Monheim-Helstroffera and Obidzinskib 2010). It is being discussed if deeper integration can alleviate some of the problems resulting from differing standards. On the other hand, transfer systems, according to which wealthy states pay poor states to resettle refugees from other poor states, could create positive externalities on third countries (Bubb et al. 2011).

With a view to the effects of asylum policies, a recent empirical study on the asylum policies in developed countries finds that a tougher asylum policy – regarding entry requirements and conditions in the receiving country – had a deterrent effect on asylum applications (Hatton 2009). It accounted, however, only for one third of the decrease. In looking more closely at the provisions which deter potential asylum seeker, the author finds that the effect is due to those policies that limit access to territory and those that reduce the proportion of successful claims. Provisions, on the other hand, that diminish the socioeconomic conditions of refugees show to have only a low deterrent effect.

Research is also carried out from the perspective of the asylum seeker identifying which migration channel he or she would opt for (Djajić 2014). According to Djajić’s model, under current laws, relatively young, skilled, and wealthy asylum seekers, who have access to credit from the family network, are found to have a strong incentive to choose to enter a country with the aid of human smugglers without proper documentation.

Under the Common European Asylum System, Europe has set up a general legal framework for its asylum policy, gradually lifting up more competences to the EU level. In trying to determine the optimal degree of harmonization of Europe's asylum laws, Monheim-Helstroffera and Obidzinskib (2010) develop a regulatory competition model. With respect to the European Union, the authors take a critical stance on ongoing harmonization efforts: In a regulatory context like the European Union, those jurisdictions closest to the external border (peripheral jurisdictions) have an incentive to choose strict admission criteria for refugees. These states would lose most from harmonization efforts that would decrease their legislative discretion. For an EU-wide policy, the question is whether the benefits from harmonization outweigh the losses of the peripheral jurisdiction. From the refugees' point of view, flexibility is warranted as it increases their chances of being admitted to the European Union. While illustrated for the EU context, the model is also more generally applicable. The fear of a "race to the bottom" in the European Union was empirically rejected as national differences in application procedures continued to exist (up to the year 2010 Toshkov and de Haan 2013). The Common European Asylum System has recently undergone some changes; various directives and regulations have been revised and will enter into force in July 2015. Bottom line is that the procedure in the member states have been more aligned, e.g., procedures to apply for asylum have been approximated by the revised Asylum Procedures Directive (Directive 2013/32/EU 2013). In the revised Reception Conditions Directive, common rules have been adopted on the issue of detention of asylum seekers. (Directive 2013/33/EU of the European Parliament and of the Council of 26 June 2013 laying down standards for the reception of applicants for international protection OJ L 180, 29.6.2013, pp. 96–116.) The revised Dublin Regulation seeks to improve the system for determining the member states responsible for the examination of the asylum application by accelerating procedures and reiterating on the decisive criteria, such as recent possession of visa or

residence permit in a member state and regular or irregular entry to the European Union. (Commission Implementing Regulation (EU) No 118/2014 of 30 January 2014 amending Regulation (EC) No 1560/2003 laying down detailed rules for the application of Council Regulation (EC) No 343/2003 establishing the criteria and mechanisms for determining the member state responsible for examining an asylum application lodged in one of the member states by a third-country national OJ L 039, 8.02.14, pp. 1–43.)

Conclusions

In this entry, we provided some insights into relevant law and economics contributions on immigration laws and policies. In the light of different forms of migration, a focus on labor/economic migration seemed appropriate, as well as a short excerpt on research topics within asylum law. The relevant contributions illustrate how different types of migrants necessarily impact countries' welfare functions differently. Immigration law is a topic, which can never be a national matter only. Hence, cooperation is a must. We have alluded to some challenges to this cooperation on regional (European Union) or even international level, resulting primarily from potential negative externalities. Legal reforms in immigration law are ongoing, and the topic stimulates a lot of potential future research.

Impact Assessment

Marie-Helen Maras

John Jay College of Criminal Justice, City
University of New York, New York, NY, USA

Abstract

Impact assessments help improve the quality of proposed legislation. It enables European Community institutions to determine the economic, social, and/or environmental costs of proposed legislation. It further identifies available options to achieve the objectives of the proposed measure and the positive and negative consequences of each of the options.

Definition

An impact assessment is a tool used by European Community institutions to identify the main policy options available to achieve the objectives of proposed legislation and the intended and unintended costs and benefits of each option. In 2003, the Interinstitutional Agreement on Better Lawmaking set forth basic principles and common objectives for the European Commission, the

European Parliament, and the Council of the European Union for their cooperation during the legislative process and nonlegislative proposals and evaluation of these initiatives (European Parliament, Council and Commission, 2003). In the interest of better lawmaking, decision-makers must have knowledge of the potential economic, social, and environmental impacts (e.g., the internal market, competition, businesses, consumers, employment, human rights, public health, species, or habitats) of initiatives (European Commission, 2009). Since 2003, the European Commission conducted impact assessments to determine this (European Commission, 2006). Specifically, the European Commission conducts impact assessments to determine the economic, social, and environmental consequences of proposed major policy initiatives, including those presented in its Commission's Legislative and Work Programme (or its Annual Policy strategy) and/or non-legislative proposals with potential significant costs (European Parliament, Council and Commission, 2005). Impact assessments identify the main policy options that are available to achieve the objectives of the proposed initiative, and all relevant stakeholders are consulted during the process. These assessments also provide the costs and benefits of a proposed initiative. The intended and unintended impacts of a proposed initiative are evaluated in quantitative, qualitative, and monetary terms; if the quantification of the consequences cannot be completed, an explanation should be provided in the impact assessment.

The cost-benefit analysis seeks to ensure efficiency in the allocation of resources among competing objectives and proposed actions. What is determined in the impact assessment is whether each policy option represents a more efficient allocation of resources (on a cost-benefit basis) than if such resources were put to alternative use, that is, another policy option. Based on these identified costs and benefits, decision-makers can make informed judgments about proposed initiatives by identifying competing policy objectives and choosing best courses of action. For certain initiatives with potential far-reaching consequences, an extended impact assessment is

conducted to provide a more in-depth analysis of the potential impacts of proposals on society, the economy, and the environment.

The impact assessment helps improve the quality of proposals and ensure that they are evidence-based. This process thus assists political decision-making and ensures a comprehensive and transparent approach to the development of legislative and nonlegislative proposals. The Impact Assessment Board, which was created in 2006, is responsible for ensuring the quality of impact assessments (European Commission, 2006). To do so, it evaluates drafts of the European Commission's impact assessments. Once an opinion is issued by the Impact Assessment Board (replaced by the Regulatory Scrutiny Board on July 1, 2015), it accompanies the impact assessment during the European Commission's decision-making on the relevant proposed initiative (European Commission, 2015). The impact assessment is then considered by the European Parliament and the Council of the European Union when evaluating the European Commission's proposals. Pursuant to the 2003 Interinstitutional Agreement on Better Lawmaking, if the European Parliament and the Council of the European Union seek to amend the European Commission's proposal in a substantial manner, they must also conduct an impact assessment, using the European Commission's original impact assessment as a starting point.

Impracticability

Hüseyin Can Aksoy
Faculty of Law, Bilkent University, Bilkent,
Ankara, Turkey

Abstract

The principle of *pacta sunt servanda* requires that agreements must be kept. However such rule is not absolute. When performance of a contractual obligation becomes impracticable, i.e., considerably more burdensome (expensive) than originally contemplated –albeit physically possible– due to an unexpected event, this would lead to adaptation of the contract to the changed circumstances or to avoidance of the contract. In the law and economics literature, impracticability has been substantially studied to figure out who should bear the risk of impracticability; and what would be the efficient remedy for such breach of contract.

Synonyms

Change of circumstances; Economic impossibility; Hardship; Imprévision; Lapse of the contract basis; Wegfall der Geschäftsgrundlage

Definition

An unforeseeable change in the circumstances, arising after the formation of the contract due to an external event, which renders the performance considerably more burdensome albeit physically possible.

Introduction

In the mid-1970s, Westinghouse Electric Corporation sold nuclear reactors to electric companies and also agreed to supply uranium at a fixed price of \$8–10 per pound. However, while the company was still obliged to deliver around 70 million pounds of uranium to 27 different buyers, the market price of uranium increased to over \$30 per pound. On September 8, 1975, Westinghouse Corporation claimed that performance of its contractual obligation would result in a loss of \$2 billion and announced that it would not honor fixed price contracts to deliver uranium. Could the Westinghouse Corporation rely on such change in the circumstances and refrain from performing its contractual obligations?

The principle of *pacta sunt servanda* requires that agreements must be kept. Accordingly, non-performance of any contractual obligation constitutes breach and may cause liability of the debtor. However such rule is not absolute. For instance, in almost all legal systems, it is a well-established principle that when performance is rendered impossible by an event of *force majeure* (e.g., war, earthquake, hurricane, etc.), the debtor will not only be released from his obligation to perform, but this will also eliminate his/her liability to compensate the damages of the creditor. However, the issue is more controversial when performance of a contractual obligation becomes impracticable, i.e., considerably more burdensome (expensive) than originally contemplated – albeit physically possible – due to an unexpected event.

On a theoretical basis, the result of impracticability might be one of the following:

- (i) The debtor can be expected to perform despite the increase in costs of performance. Correspondingly, if the debtor fails to perform, he/she has to compensate the damages of the creditor. In such cases, the scope of the recoverable damages (reliance damages or expectation damages) of the creditor must also be determined.
- (ii) Impracticability can be regarded as an event, which excuses the debtor. In such cases, the

creditor can neither ask for performance nor compensation. In return, the creditor does not perform either. However it must still be decided if impracticability excuses the debtor *ipso facto* or it grants the debtor a right to avoid the contract.

- (iii) It can be argued that impracticability does not lead to an absolute excuse or the avoidance of the contract but only to the adaptation of the terms of the contract to the changed circumstances. In other words, either the parties themselves or the court adapts the contract to the changed circumstances and reestablishes the balance between the debtor's obligation and the creditor's counter-obligation.

Impracticability in Modern Legal Doctrine

The modern legal doctrine regards impracticability as an exception to the principle of *pacta sunt servanda* provided that the performance becomes excessively difficult for the debtor due to an external event, which could not be foreseen at the time of the conclusion of the contract, and under the new circumstances the debtor cannot reasonably be expected to perform as stipulated in the contract.

It must be emphasized that the border between impossibility and impracticability is hard to draw. Despite their similarities, these two concepts have important differences as well. Since impossibility is regarded as an objective and permanent obstacle to performance, it causes expiration of the primary obligation of the debtor. This follows from the fact that the debtor cannot be expected to perform what is impossible. On the other hand, in case of impracticability the obligation is – at least theoretically – still possible, however at enormous and unexpectedly high cost. Therefore, in such cases, the primary tendency is to preserve the contract, and it is generally ruled that the contractual balance must be restored through adaptation of the obligations of the parties to the changed circumstances. However, if such adaptation is not possible, the second option is the avoidance of the contract. This would result in

elimination of the obligations of both parties, including compensation liability.

When performance becomes more burdensome – albeit possible – some legal orders, for instance, the German Civil Code, distinguish between two case groups, which lead to different legal consequences. According to §275 II BGB, if there is gross disproportionality between the creditor's interest in performance and the debtor's interest in non-performance (i.e., required efforts and expenses to perform), the debtor may refuse to perform. The classical example of this case is the ring which falls into the sea. In this case, the legal consequence of impracticability is the same as that of impossibility: the debtor's obligation to perform the primary obligation extinguishes. A second group captures those cases, in which the cost of performance rises enormously, just as in the first group, after the conclusion of the contract, but the value of the contract (performance) rises too. In such cases, which fall under §313 BGB, there is no disproportionality, but the circumstances which became the basis of the contract significantly change. For example, an art dealer buys a painting of a famous painter from a gallery which the gallery must still buy on the market. But before the purchase by the gallery, a fire in a museum destroys many paintings of the particular painter, which increases the price of the bought painting by the factor 10. Here the event which makes the performance so expensive increases proportionately the interest of the creditor in performance. In this case, the debtor's obligation to perform the primary obligation would not extinguish but the legal consequence would be adaptation of the contract by raising the price. Revocation would be the secondary option, if adaptation is not possible or one party cannot reasonably be expected to accept adaptation.

The practical difference between the scopes of these provisions is the following: when the value of the performance increases, the creditor's interest in receiving performance increases proportionally as well; hence the performance which has become burdensome for the debtor is not disproportionate to the interest of the creditor. Therefore, an objective increase in the market price of the good is separated from the cases, where the

procurement of the good has become particularly costly for the specific debtor.

Economic Analysis of Impracticability

Impracticability has been substantially studied in the law and economics literature. In fact, economic considerations might play an important role in drawing the line between a bearable difficulty and “excessive difficulty” (impracticability). Moreover, economic reasoning might be useful in determining when the parties can resort to avoidance of the contract instead of adaptation to the changed circumstances.

Risk-Bearing Perspective

In the earlier stages, authors approached the issue from the economic theory of efficient risk bearing and imposed the entire results of impracticability on either of the parties (Posner and Rosenfield 1977; Joskow 1977). Within this stance, in their pioneering study, Posner and Rosenfield argue that a discharge question arises only if the contract has not assigned the risk in question (to either of the parties) and the event, giving rise to the discharge claim was not avoidable by any cost-justified precautions (of the debtor). Provided that these two conditions are met, the authors argue that the loss should be placed on the party who is the superior (the lower-cost) risk bearer. Accordingly, the superior risk bearer can be figured out by three factors: knowledge of the magnitude of the loss, knowledge of the probability that it will occur, and costs of self-insurance or market insurance. For instance, the party, who is in the position to prevent the materialization of the risk or to insure the risk at a lower cost, would be the superior risk bearer. In the end, if the debtor is found to be the superior risk bearer, he/she must perform despite the increase in the costs of performance. However should the creditor be in the position to bear the risk, the debtor would be discharged.

Efficient Remedy Perspective

Posner and Rosenfield’s all-or-nothing approach, which shifted the entire risk to either of the parties, was later on questioned by some authors, who

focused their studies on designing efficient remedies for breach of contract. Instead of deciding who should bear the entire risk, these authors associated impracticability with efficiency and focused on dividing the risk between the contracting parties. Within this context, considering the efficiency of the remedy in a given case, the result of impracticability could vary between expectation damages and no remedy.

With efficiency considerations, it is generally argued that except for some very rare cases, discharge of the debtor would not yield to efficient results (White 1988; Sykes 1990). As a matter of fact, associating impracticability with discharge of a contract will negatively affect the risk bearing of the parties. Moreover the availability of discharge as a remedy will create high breach incentives on the debtor.

Even if it is accepted that impracticability should not lead to discharge of the debtor except for exceptional cases, it is argued that neither expectation damages nor reliance damages must be covered in all cases of impracticability. In fact such decision must be rendered on a case-by-case analysis. Within this stance, some authors propose to focus on the risk aversion of the parties while making a choice between the imposition of expectation damages and reliance damages (Shavell 1980; Polinsky 1983) or even between expectation damages and no damages (Sykes 1990). Others argue that the parties’ expectancies at the time of the conclusion of the contract regarding the change of circumstances will be decisive on the choice between expectation and reliance damages (Eisenberg 2009).

Another group of authors argue that in cases of impracticability, the appropriate remedy would be adjustment of the contractually contemplated price (Speidel 1981; Trakman 1985; Trimarchi 1991). The main arguments of these authors is that in cases of absolute uncertainty (in systematic risks such as inflation or international crises, which affect the economy as a whole), the “superior risk bearer” criterion is inappropriate and insurance is not an adequate option (Trimarchi 1991). Moreover, it is asserted that the price adjustment of the court redresses the advantaged party’s opportunistic conduct as the advantaged

party has the duty to cooperate and bargain in good faith ex-post (Speidel 1981).

Another proposal is that the total surplus of the contract must be taken into consideration, when deciding on the result of impracticability (Aksoy and Schäfer 2012). Within this stance, following the increase in costs of performance, if the contract still generates positive surplus, there is no reason to avoid the contract. In this case, if the risk was very remote and both parties failed to consider the risk, the obligations of the parties can be adapted to the changed circumstances. However if the total surplus is obviously highly negative and if this is observable by a third party like the judge, the contract would be avoided. In this case, in addition to the excessive and low probability cost increase, the increase in relation to the interest of the buyer (consumer surplus) triggers avoidance of the contract.

Finally, it must be emphasized that the necessity of the excuse doctrines is disputed itself. For instance, there are some authors who question the well-recognized assumption that parties cannot allocate risks under uncertainty. According to Triantis (1992), the question is not whether a particular risk is allocated or not, but at what level it is allocated. The author argues that even if all risks are not “explicitly” allocated, they can be allocated under broader risk groups. For instance, an increase in the transportation costs due to increase in oil prices following a nuclear accident in the Middle East cannot be “explicitly” anticipated, but the parties may allocate the broader risk of a large increase in oil prices for any reason. Therefore, allocation of risks must be left to the parties and the role of the contract law should be restricted to interpretation and enforcement of the risk allocations of the parties.

Incomplete Contracts

Maria Alessandra Rossi
Department of Economics and Statistics,
University of Siena, Siena, Italy

Abstract

The notion of incomplete contracts refers to the circumstance that some aspect of contractual parties' payoff-relevant future behavior or some relevant payoff in future contingencies is unspecified in the contract and/or unverifiable by third parties. This may be attributed, by and large, to three different causes: high enforcement costs entailing unverifiability by third parties such as courts or arbitrators; the transaction costs that arise from uncertainty about future events, from the contractual parties' bounded rationality, and from judges' bounded rationality; and, finally, from asymmetric information. Different research programs in the economics of contracting explore the implications of these different sources of contractual incompleteness, providing insights addressing an extremely wide range of contractual issues, including the theory of the firm, the theory of corporate finance, the analysis of formal and informal institutions, regulation and public ownership, innovation and intellectual property, and international trade. The extent to which the notion of contractual incompleteness also has relevant normative implications for the law and economics of contract regulation is an issue currently debated.

Definition

Contracts can be considered incomplete, from an economic perspective, when some aspect of parties' payoff-relevant future behavior or some relevant payoff in future contingencies is unspecified in the contract and/or unverifiable by third parties. In other words, an incomplete contract is a contract that is insufficiently state-contingent, so that some or all of the parties to the transaction are unsure as to the effective payoffs they will receive in any future state of the world. When the cause of incompleteness is attributed entirely to the fact that some aspects of the transaction are observable to the parties but unverifiable by third parties, an "incomplete contract approach" is said to be adopted.

Introduction

The notion of incomplete contract belongs more to the realm of microeconomic theory than to the law and economics approach *stricto sensu*. The scholarly contributions that have explored the wide-ranging implications of the notion have indeed focused mostly on the positive analysis of contractual parties' behavior with regard to the choice of the contractual form that may best limit the negative effects of incompleteness and on the comparative analysis of the choice of the governance arrangement most apt to complement or substitute for the incomplete contract. Thus, most of the literature that attributes relevance to the notion of contractual incompleteness does not directly address the issue of the effects of legal rules on contractual parties' behavior that is the core concern of the law and economics analysis of contracts. In other words, the literature on incomplete contracts deals mostly with the mechanics of private contracting rather than with contract law. There is, nonetheless, some overlap, to the extent that the economic notion of incomplete contract and the associated research programs provide normative implications for contract interpretation and contract regulation.

This entry provides an overview of the concept, considering first its meaning according to the

different theories that have highlighted its relevance and then its many implications in a wide range of research domains. The insights drawn from the notion of incomplete contract have indeed been fruitfully applied to a wide number of specific issues, including the theory of the firm, the theory of corporate finance, the analysis of formal and informal institutions, regulation and public ownership, innovation and intellectual property, and international trade. The normative implications of contractual incompleteness for the law and economics of contract regulation are also briefly reviewed.

The Meaning of Contractual Incompleteness

A contract may be said to be literally incomplete if it contains a true “gap,” namely, if it does not contain provisions relating to some event or circumstance that may arise in the future (*unforeseen contingency*) and therefore does not define parties’ behavior in such circumstances. While this notion of contractual incompleteness has been adopted, implicitly or explicitly, in a number of law and economics analyses, the expression “incomplete contract” is more commonly understood to refer to the strictly economic version of the concept, which introduced into microeconomic theory the general insight that real-world contracts may significantly diverge from the perfect, fully state-contingent contracts depicted by the theory of perfectly competitive markets.

Thus, incomplete contracts may be defined, from an economic standpoint, as insufficiently state-contingent contracts (see, e.g., Schwartz 1998). The economic literature identifies three possible reasons for their existence, to which correspond, by and large, three research programs in the economics of contracting.

The first reason for contractual incompleteness is given by enforcement costs and is emphasized by the research program inaugurated by Sanford Grossman, Oliver Hart, and John Moore and defined as “incomplete contract theory,” “new property rights approach,” or GHM theory.

According to this perspective, contracts are incomplete because some aspects of the transaction are observable by the parties but not verifiable by a third party in charge of enforcement – a judge or an arbitrator. In other words, the origin of contractual incompleteness should be attributed to a problem of asymmetry of information between the contractual parties and a relevant outsider – a judge or an arbitrator – in charge of enforcing the contract.

The second source of contractual incompleteness – emphasized by new institutional and transaction cost economics – is given by the transaction costs that arise from uncertainty about future events, from the contractual parties’ bounded rationality, which limits their ability to account *ex ante* for all the future contingencies that may affect parties’ contractual payoffs, and from judges’ bounded rationality. The relevant transaction costs may be of at least four main types: (1) the cost of foreseeing all the possible states of the world that may materialize during the contractual relationship; (2) the cost of negotiating and finding an agreement about the appropriate course of action parties should take in any future state of the world; (3) the cost of describing *ex ante* in a contract the characteristics of what is traded and/or the parties’ effort for each possible contingency; and, finally, (4) enforcement costs (Williamson 1985; Hart 2008). According to this perspective, incompleteness may also be endogenous because parties rationally decide to save on contracting costs when transaction costs exceed the corresponding benefit.

A third cause of contractual incompleteness is asymmetric information between contractual parties, explored by principal-agent theory. This perspective entails that contracts are voluntarily left incomplete because more complete contracts would create opportunities for moral hazard or adverse selection. Making payoffs contingent on future states of world that cannot be symmetrically observed by parties may indeed allow the informed party to misrepresent the state of the world that has materialized so as to increase her payoffs. Similarly, in some instances, a complete contract may not be chosen because it reveals to the counterpart valuable private information. In

all of these cases, incompleteness is entirely endogenous as it emerges from the equilibrium choices of players whose actions are not constrained by bounded rationality or asymmetric information with respect to third parties. This third source of contractual incompleteness is worth mentioning for completeness, but it should be noted that the notion of “incomplete contract” is generally evoked by reference to transaction and/or enforcement costs.

Thus, there is some debate on the root causes of contractual incompleteness. The debate goes as far as to question the very existence of a theoretical foundation for the notion of incomplete contracts and to suggest the superiority of complete contracting approaches, related to implementation theory and mechanism design (Schmitz 2001). The main criticism to the notion of incomplete contracts is that the assumption of unverifiability by third parties appears weak if parties are symmetrically informed (Maskin and Tirole 1999). Payoff-relevant information is generally only partly unverifiable and parties may invest resources to increase verifiability. Moreover, symmetrically informed parties may adopt complex revelation mechanisms that can be negotiated ex ante and that ensure that both parties will have incentives to reveal their true preferences ex post, so as to ensure efficient outcomes. It should be noted, however, that these complex contracts are seldom observed in practice.

The Holdup Problem

Contractual incompleteness matters, from an economic standpoint, in so far as it affects the realization of Pareto-efficient exchanges. Most of the incomplete contracting literature focuses on circumstances when this is the case because the contract involves some form of specific investment and at least an opportunistic party (Williamson 1985).

Investments specific to particular assets or relationships are investments whose economic value is much higher within the relationship and provided that the investing party has access to the relevant assets rather than outside the relationship

or in absence of access to the assets. In other words, the ex post value of specific investments outside of the relevant transaction is much lower than their ex ante next best alternatives. Thus, once specific investments have been incurred, the contractual parties become to some extent locked into each other (what Oliver Williamson has famously dubbed the “fundamental transformation” of a standard transaction into a bilateral monopoly).

Agents who make specific investments are therefore exposed to the risk of counterparts’ opportunistic behavior because, to realize the surplus from their investments, they need the cooperation of their contractual counterparts and they require access to a particular set of assets. However, precisely because of this *lock in effect*, contractual counterparts may behave opportunistically and try to renegotiate the terms of the original contract so as to obtain a greater share of the total surplus (this is the substance of what is called the “holdup problem”). Since the level of specific investment is not verifiable ex post, the extent to which an individual will be able to appropriate the surplus from his investment cannot be determined ex ante via the original contract and depends on his ex post bargaining power. The source of inefficiency therefore lies in the fact that the threat of holdup constitutes a deterrent to the ex ante realization of unverifiable specific investments, so that some Pareto-efficient transactions may be inhibited.

Incomplete Contracts and the Theory of the Firm

The first and foremost application of the incomplete contracting framework concerns the theory of ownership and vertical integration developed by the incomplete contracts approach on the basis of insights first proposed by Oliver Williamson. This theory explains the very existence and the boundaries of the firm by emphasizing the important economic function of the allocation of property rights over physical or nonhuman assets in a situation of incomplete contractibility (Grossman and Hart 1986; Hart and Moore

1990). When contracts are incomplete, ownership of physical or nonhuman assets is indeed important because it influences parties' threat points in the ex post bargaining and therefore the division of ex post surplus. This is because "the owner of an asset has residual control rights over that asset: the right to decide all usages of the asset in any way not inconsistent with a prior contract, custom or law" (Hart 1995, p.30). Ownership ensures ex ante the owner that he will be able to dispose ex post of the asset and will not be excluded from its use. The increased bargaining power at the renegotiation stage provides the owner with a greater incentive to invest with respect to non-owners.

The incomplete contracts approach thus conceptualizes the firm as a collection of assets over which the owner has residual rights of control and proposes a theory of optimal ownership allocation according to which ownership rights over non-human assets should be assigned to the agents who value them the most, i.e., to the parties who have to make the most relevant and specific investments in human capital. Assuming that parties may efficiently bargain ex ante on the allocation of ownership rights, the theory also predicts that efficient ownership allocations will tend to emerge in equilibrium (for a survey of contributions developing this approach, see Aghion and Holden, 2011).

The solution envisaged represents, however, only a second-best solution and the theory has the merit of highlighting also the costs of ownership allocation as a mechanism to align incentives. The most relevant of these costs is that the incentive provided through the allocation of residual control operates only with respect to the owner, while incentive problems persist with regard to non-owners. When the number of agents required to make specific investments is high, the gap between the first-best and the second-best solutions will be particularly wide, and the allocation of ownership rights will therefore display a limited efficacy as an incentive mechanism.

The incomplete contracting approach provides a framework for the comparative analysis of governance structures that may explain vertical integration choices and the scope of the firm's boundaries. The theory is, however, subject to

a major criticism: there is some logical tension in assuming that agents may not sign complete contracts specifying required specific investments but that they can perfectly foresee ex post payoffs in order to bargain on the optimal ownership allocation.

The key role played by the allocation of residual rights of control in an incomplete contract framework has been explored by this literature also by a different angle. Rather than focusing on the allocation of ownership as a mechanism to align incentives, a large number of contributions has explored the design of contractual procedures that define the ex post renegotiation framework in a way that, by constraining renegotiation, suitably allocating bargaining power and defining default options allows to overcome the holdup problem (Chung 1991; Aghion et al. 1994). The mechanisms thus defined (*option contracts*) allow to achieve first-best outcomes but require higher degrees of verifiability than GHM-style models because the external enforcer is assumed to be able to recognize who is the opportunistic party (for a survey, see Schmidt 1998). This strand of research seeks to explain contractual behavior rather than firm's organizational choices. The main limit of this approach stressed by critics is that the theory's basic insights are very sensitive to underlying assumptions.

Incomplete Contracts, Transaction Costs, and Institutions

Starting from a somewhat stronger notion of contractual incompleteness than simple observability plus non-verifiability, the new institutional and transaction cost research program focuses on the comparative analysis of the institutional arrangements designed to mitigate the effects of incompleteness (see, e.g., Brousseau and Glachant 2002). Given that agents have limited cognitive resources and face strong (Knightian) uncertainty, according to this perspective, they devise their contractual relationships in ways that allow for the minimization of transaction costs. The solutions that emerge from transaction cost

minimization vary from bilateral contracts to formal and informal institutions, all of which may perform similar functions in terms of ensuring effective enforcement of the contractual relationship. The contractual relationship is conceptualized as a sophisticated object designed to provide safeguards for specific investments, promote parties' commitments, and guarantee performance through the definition of negotiation procedures, supervision mechanisms, and conflict-resolution tools. It implements what this literature calls a "private order" meant to discipline parties' behavior.

The core issue involved by contract design is given by the trade-off between opportunism and efficient adaptation (see, e.g., Nicita and Pagano 2005). Contracts may be long or short, detailed or open-ended. The choice among these features depends on their relative costs and benefits: when contract duration is long, a very detailed contract may be chosen with the purpose of minimizing the risks of opportunism at the cost of incurring higher ex ante transaction costs and lower ex post flexibility. At the same time, the broader and more open-ended the contract, the higher the flexibility allowed to the parties in order to efficiently react and adjust the mechanics of their relationship to unforeseen contingencies. This basic trade-off gives rise to the emergence of contracts with different durations and different degrees of ex ante specification of parties' obligations, according to the nature of the underlying relationship and to the characteristics of the institutional environment.

Institutions play a key role for contractual design because they provide the default rules of the game that parties may choose instead of elaborating more complex bilateral arrangements. Relevant institutions include, of course, public institutions in charge of enforcement such as the legal system and the judiciary but also a wide range of other institutional arrangements that have a private nature, both formal (codes of conduct, business associations, standard-setting organizations, etc.) and informal (customs, reputation, corporate culture, etc.) (North 1990). The nature of the institutional environment influences the choice of contractual terms and the ability of given contracts to implement efficient outcomes.

The logic of transaction cost minimization of the new institutional and transaction cost approach is meant to explain the emergence of different institutional arrangements as efficient responses to given transactional characteristics and features of the institutional environment. However, it does not easily lend itself to explain the persistence of inefficient institutions and private arrangements. The literature on institutional complementarities (Pagano and Rowthorn 1994; Aoki 2001) also starts from the notion of contractual incompleteness but provides an explanation for inefficiencies. It focuses on the existence of multiple equilibria across different choice domains: agents are unable to coordinate their choices across different domains, and therefore, their choices in one domain are influenced by the choices made in other domains, giving rise to a multiplicity of institutional arrangements, each of which constitutes a Nash equilibrium with self-reinforcing properties. Depending on initial conditions, inefficient equilibria may emerge and persist through time, unless exogenous shocks intervene to shift the system toward a different equilibrium.

Incomplete Contracts and Corporate Finance

The incomplete contract notion has shed new light also on the analysis of the determinants of the choice of a firm's financial structure, providing a perspective that highlights for the first time the importance of corporate finance choices for incentives. The incomplete contracts approach to corporate finance allows to overcome some of the limits of the so-called trade-off theory of the optimal capital structure of the firm according to which the optimum debt-equity ratio is chosen by equating the marginal benefit in terms of tax savings from the use of debt (which the tax treatment renders cheaper than equity after tax) with the expected marginal bankruptcy cost. This theory, prominent in corporate finance, does not address the issue of the impact of the capital structure on stakeholders' incentives to make firm-specific investments and therefore on firm performance.

Adopting an incomplete contracts approach allows, by contrast, to trace a link between corporate finance and the generation of a firm's cash flow by analyzing the effect of alternative financial structures on the allocation of control rights. It is when enforcement of both financial contracts and managers' incentive contracts is limited that the allocation of residual rights of control matters (Bolton 2013). This is because financing choices affect the distribution of decision powers in the event of unforeseen contingencies and therefore shape *ex ante* incentives.

This perspective thus provides an economic justification for the use of debt different from tax advantages: debt is a form of financing that ensures a flexible and contingent allocation of control rights between the investor and the entrepreneur (Aghion and Bolton 1992). Recourse to debt implies that control rests in the hand of the entrepreneur in case a good state of the world materializes and that it shifts in the hands of the financier in case of a bad state of the world. This provides safeguards to both parties: to the financier, who is shielded against excessive losses in the bad state, and to the entrepreneur, who is protected from the risk of losing control in the good state.

Incomplete Contracts and Innovation

Both contractual incompleteness and asset specificity appear especially pronounced in the context of innovative activities. Innovation is indeed a collective, cumulative, and highly uncertain process that involves specific investments by a large and varied number of firm stakeholders (financiers, managers, workers, etc.) who contribute financial, physical, and intellectual resources to a common endeavor whose final outcome is often to a large extent unpredictable and impossible to specify in a detailed contract. The risk of underinvestment associated to the holdup problem is thus magnified in this context, as the collective nature of the innovative process multiplies the instances of potential holdup.

Acknowledgement of these features has prompted a number of contributions exploring the

implications of incomplete contracts for firms' ability to innovate. This literature takes as a starting point the basic intuition of the incomplete contract approach, namely, that absent the possibility to write complete contingent contracts, the rules affecting the allocation of residual rights of control over the relevant assets deeply influence stakeholders' incentives to invest. Therefore, this stream of research focuses on the relationship between the institutions, market forces, and internal governance arrangements that jointly define firms' corporate governance structure and innovative performance. In an incomplete contracting framework, corporate governance rules matter because they affect the extent to which financial investors are guaranteed a return for their investments, and therefore the price at which there are willing to provide the firm with the funds necessary to undertake innovative projects, and because they affect the distribution of residual rights of control within the corporation, and therefore stakeholders' incentives to make specific investments in human capital. A rich theoretical and empirical literature has uncovered the many facets of firms' corporate governance that may have a bearing on innovation, including the degree of ownership concentration, owners' identity, firms' capital structure, the extent of workers involvement in firms' decision-making processes, and institutional factors such as the degree of unionization and the rules disciplining takeovers (for a survey, see Belloc 2012). A related strand of research adopts an incomplete contract framework to explore the costs and benefits of the allocation of intellectual property rights as an incentive mechanism (Aghion and Tirole 1994; Pagano and Rossi 2004).

Incomplete Contracts and International Trade

Another domain where it is natural to assume the presence of contractual incompleteness is international trade. International transactions occur in absence of effective enforcement systems, since uncertainties exist as to applicable laws when contracting parties reside in different countries,

existing international conventions and trade fora are limited at best, and implicit contracts based on repeated interactions are scarcely effective in curbing opportunism. The notion of incomplete contracts has indeed been fruitfully applied in open-economy environments to study the issue of firm organization and vertical integration in the international context so as to explain the determinants of multinational activity and the structure of international trade flows. In particular, attention has been devoted to explaining, on the basis of GHM-style arguments, why multinationals tend to integrate capital-intensive productions of intermediate inputs and to outsource labor-intensive productions (Antràs 2003). According to this literature, the choice reflects the allocation of property rights to the party who has to make the most important specific investment.

The other main strand of research exploring the implications of the concept of contractual incompleteness in an open-economy environment aims at explaining countries' comparative advantage in the production of goods requiring relationship-specific investments. Since countries differ in their ability to ensure contract enforcement, and since the effectiveness of enforcement affects incentives to make relationship-specific investments, countries with stronger contract enforcement will have a cost advantage in productions requiring relatively higher degrees of relationship-specific investments. This may explain patterns of international trade as well as firms' geographical location (see, e.g., Nunn 2007).

These two strands of research do not exhaust by any means the landscape of contributions linking incomplete contracts to international trade but nonetheless provide a useful introduction to the nature of the issue addressed. The literature on trade and institutions inspired by the incomplete contracts notion has, indeed, flourished both theoretically and empirically in recent years, providing insights for analyzing trade policy choices, understanding the role of power in international transactions, the financial structure of multinational firms, and many other globally relevant issues (for surveys, see Antràs 2013; Helpman 2006).

Incomplete Contracts and the Law and Economics of Contract Regulation

From a strict law and economics perspective, the economic problem of incomplete contracts matters because it is at the roots of the legal problem of contract regulation, which includes the issue of contract interpretation. Contractual incompleteness implies that there is a role for the State in filling the gaps left by parties by interpreting the contract, supplying a common framework and vocabulary to contracting parties, supplying default rules, and eventually regulating the contracting process through other means. What exactly this role should be has, however, so far not been fully defined by the incomplete contracts literature.

A relevant point of view in this regard holds that the notion of contractual incompleteness should be taken to suggest that the State should refrain from attempting to provide efficient default rules to "complete" contracts because it is highly unlikely to possess more accurate information or to incur lower transaction costs than the parties in drafting the relevant provisions (Hermalin and Katz 1993). Moreover, when contracts are endogenously incomplete, any attempt to provide default rules that modify parties' original contractual arrangement may undermine the latter by modifying the terms of the chosen renegotiation game. A further implication of this line of reasoning is that specific performance should be preferred to any attempt to regulate contracts by supplying default rules or imposing efficient solutions (Schwartz 1998).

A different viewpoint holds that the normative implications of the incomplete contracting literature are limited and inconclusive, mostly because the latter does not appear to successfully predict either contract content or interpret legal doctrines such as the penalty doctrine (Posner 2003).

Conclusion

The notion of incomplete contract has gained wide currency in both microeconomics and law and economics. The concept appears to some extent elusive: while most would agree that

non-verifiability of contractual terms by third parties and insufficient state-contingency of the contract are key elements of the definition, there is some theoretical debate on other relevant aspects and on the very meaning and foundations of the concept. In spite of these debates, however, the concept has proven to be rather versatile, as it underlies, in one form or another, a diverse collection of both theoretical and empirical studies. Starting from the basic application in explaining the size and the boundaries of the firm and in motivating comparative analysis of institutional arrangements, the notion of contractual incompleteness has spurred research in a wide range of more specific domains that has refined our understanding of firms and institutions. The appropriate way in which these insights should be incorporated into the analysis of the effects of legal rules on economic agents' behavior is, however, still somewhat controversial and deserves further study.

Independent Judiciary

George Tridimas

Department of Accounting, Finance and Economics, Ulster University Business School, Belfast, Northern Ireland

Abstract

After describing the closely related concepts of judicial independence and independent judicial review of policy, this entry offers an overview of four issues: (1) Reasons for establishing an independent judiciary, including its ability to resolve problems of information asymmetry between citizens – principals and public officials – agents, transform constitutional declarations to credible commitments and provide a mechanism of political insurance; (2) mechanisms for appointing judges and the jurisdiction of courts; (3) modeling the role of the judiciary as an additional veto player in games of collective decision-making and policy implementation; and (4) the judiciary as an explanatory variable and its effect on economic variables of interest like economic growth and the size of the government.

Definition

Judicial independence means that courts enforce the law and resolve disputes without regard to the power and preferences of the parties appearing before them (La Porta et al. 2004). Its theoretical antecedents are traced to the Enlightenment, and its application in practice dates to the US Constitution. Judicial independence is an indispensable part of the rule of law. The rule of law requires that laws apply equally to both ordinary citizens and public officials and that they protect the rights of

individuals against the power of the state in both the political and economic spheres. In this respect the rule of law and judicial independence are inextricably linked with liberal democracy. The literature on the topic is enormous and cuts across different disciplines including law, economics, politics, and sociology. It is not possible to do justice to this scholarship in the confines of the present essay; rather its aim is to present a summary of the main issues. First, it considers the rationale of judicial independence and the closely related judicial review. Second, it looks at the institutional arrangements for judicial independence. Third, it considers how independent courts are modeled in the collective choice framework. Fourth, it discusses some evidence on the effects of judicial independence on economic variables of interest. These issues are analytically treated as separate but are best understood in relation to each other.

Rationale for Judicial Independence

Judicial Independence and Related Concepts

An independent judicial authority is necessary to resolve disputes and maintain the rule of law which are prerequisites for the functioning of a market economy and a free society. In general, two parties in dispute may resolve their differences by fighting violently against each other or by asking a third party to arbitrate. Realizing that fighting may result in serious inefficiency (destruction of life and property), they may ask a third party to adjudicate and agree to abide by its ruling. They will only do so, however, if they are reasonably confident that the adjudicating party is a neutral and unbiased referee. Disputes may emerge between private entities (citizens, companies, or other organizations), between private entities and the state which among other cases is always a litigant in cases of economic regulation and criminal acts, and between different state organizations (central government, local authorities, nationalized industries, and other public law bodies). Judges with the power to issue binding rulings must then be shielded from the threat of corruption and intimidation by both private litigants and the arms of the state.

However, the very act of referring a dispute to a mediator generates a new conflict: When the dispute resolver declares a winner and a loser, his legitimacy may be undermined leading to the collapse of the adjudication process and its benefits. The reason is that a ruling which obliges parties to behave in a particular way (take specific actions, pay damages, fines, sentence to prison) creates a two-against-one situation (winner and judge against the loser), which is resented by the loser. In order to overcome such problems, arbitrators base their rulings on generally accepted principles of justice and conduct as expressed in formal laws and informal norms and adopt rhetoric of normative justification. The two-against-one problem is even more pronounced in cases where the state is one of the disputants. A delicate balancing act then must be performed between the need to resolve disputes, protecting the independence of the judge, and ensuring that he is perceived as serving only notions of justice.

Closely related to judicial independence is the function of judicial review of policy, where courts may examine and subsequently ratify or annul laws and policy measures, passed by the legislature and enacted by the executive branch of government, for their compatibility with the constitution or other relevant statutes (like declarations of basic rights), and have been enacted according to the stipulated procedures (Stone Sweet 2002). Similarly to ruling in disputes between private parties, judicial review of policy is meaningless unless the reviewing judge is independent of the government. Two further related concepts are those of judicial activism and judicial discretion. Judicial activism is the propensity of courts to query the decisions of elected officials and range from “nullifying acts of the legislature, to abandoning neutral principles, to deciding cases in a politically ‘liberal’ or ‘conservative’ fashion” (Hanssen 2000, p. 538). Judicial discretion is understood as the degree to which the judiciary can implement rulings without being overruled by one of the other branches of government (Voigt 2008).

The interdisciplinary literature analyzing judicial independence can be divided into two strands. The first includes scholarship that treats a

politically independent judiciary as an endogenous variable and examines the reasons for its establishment and the characteristics and degree of its political independence. The second strand considers courts as an explanatory variable and seeks to understand how it affects other political and economic variables of interest, mainly but not exclusively economic growth.

Reasons for Judicial Delegation

A number of in truth complementary explanations of an independent judiciary and its review powers have been proposed in the literature. For a review complementary to the issues taken up in the present section, the interested reader is referred to Harnay (2005). In all cases the starting point is the constitution. Constitutions, written or unwritten, and other fundamental charters specify the rules by which collective decisions are made and the constraints set upon the government and the citizens. They contain declarations of general principles, procedures, organizational forms, and rights and obligations, which, in the absence of complete information and perfect foresight about future changes in tastes and technology, are rendered as incomplete contracts riddled with problems of interpretation and enforcement. The judiciary is the arm that interprets and enforces the constitution, all ordinary laws, and policy measures, and for this reason judicial independence and judicial review are often analyzed jointly.

Modern scholarship uses the insights of the economic analysis of institutions and game theory to examine the benefits of delegation to courts; see Law (2009) and Tiede (2006). Delegation of decision-making by uninformed principals, like the citizens or their political representatives, to the judiciary, a specialized agent, offers several benefits. (a) It resolves problems of information asymmetry as courts develop the relevant expertise in resolving disputes and interpreting and enforcing the law, which subsequently allows specialization of labor and increases welfare. (b) By taking resolution of constitutional disputes away from partisan politics and handing it to “politically disinterested” judges, judicial independence promotes the long-run interests of citizens.

Politicians are better informed than ordinary citizens and exercise discretionary actions which opens up the opportunity for abuse of power to pursue their own interests at the expense of the rest of the society. Citizens may be protected from such abuses by subjecting politicians to elections, which allows voters to confirm or reject politicians, and by setting up checks and balances, where decision-making is divided between different arms of the government and each arm can block the actions of the rest. An independent judiciary is part of the latter mechanism. As it does not need to pander to short-term shifts in public opinion, it may be trusted to look after the long-run interests of citizens and control politicians. Thus, judicial independence is a mechanism that transforms constitutional declarations to credible commitments. Specifically, citizens wish to protect certain individual rights when the cost suffered by someone who is denied that right is very large relative to the gain obtained by others when the right is denied and when those who grant the right are uncertain whether they will be protected or harmed by that right (Mueller 1991). For example, pronouncements of individual freedoms, property rights, protection of minorities, nondiscriminatory taxation, and the like can be trusted by the citizens, who safe in this knowledge will develop longer time horizons increasing investment, growth, and welfare (Maskin and Tirole 2004). Note that in the credibility rationale of judicial delegation, the independent judiciary protects the interests of citizens against a mighty government and political competition and judicial review are substitutes. This is based on an underlying conflict between on the one hand politicians (who irrespective of partisan ideologies pursue their personal interests against those of the citizens) and on the other hand all the citizens.

(c) Contrary to the credibility view, the political insurance view of an independent judiciary considers the conflict between political groups competing for office and focuses on independent courts as a mechanism of political insurance. This approach builds on the famous thesis of Landes and Posner (1975) that a judiciary independent of the current legislature adds permanence to the distributive gains secured by the original winning

political coalition. In essence the argument runs as follows (Stephenson 2003; Hanssen 2004a, b; Tridimas 2004, 2010). Constitutional judicial review implies that courts may prevent the election winner to implement his favored policy measures if found to violate the constitutional arrangements and the rights of citizens. However, in exchange for this constraint, when the same party is out of office, its opponent may also be prevented from implementing his favored policy. Hence, the losers of the political contest can use the review process as a mechanism to minimize the losses inflicted to them from the measures taken by the electoral winner. When political groups anticipate that they will not win every election and therefore they will be out of power, constitutional judicial review is a useful mechanism to restrain those in control of the government. Constitutional review by an independent judiciary lowers the risks associated with the uncertain outcomes of collective choice. On the above reasoning, one expects judicial review to be more pronounced in politics where political competition is strong and parties alternate in office. In the political insurance framework given the probability to win an election and the differences in the preferences of competing political groups, each political group is better off when an agent decides policy but prefers to delegate policy making to an “ally,” that is, an agent which has preferences similar to its own. See Cooter and Ginsburg (1996) and Hayo and Voigt (2007) for an empirical investigation of the determinants of judicial independence.

Note that delegating thorny issues to the judiciary may offer short-run benefits to politicians who this way shift blame for unpopular decisions to independent agents to escape electoral punishment (Fiorina 1986). However, such delegation to the courts decreases the ability to claim credit for policies with a favorable impact. When the expected gains from shifting the blame exceed the expected losses from foregoing credit, the politician will choose to refer policy making to the judiciary. Shifting of responsibility is easier if the judiciary is perceived by the electorate as independent of the other branches of government. However, the latter view loses its explanatory

power when voters cannot be fooled and recognize the politicians' play.

Institutional Arrangements for Judicial Independence

Judicial review of the acts of government is the most politicized aspect of the behavior of courts. Judicial involvement in the political process and collective choice raises a fundamental question: Decision-making by an independent but unelected judiciary may go against deep-seated notions of majority decision-making and electoral accountability. As soon as discretionary powers are granted to the judiciary, a new principal-agent problem arises: A judiciary which is strong enough to block the legislative majority is also strong enough to pronounce rulings to pursue its preferences. What guarantees are there that the independent judiciary will not pursue its own interests at the expense of the citizens that it is supposed to protect? This is the well-known problem of "who will guard the guards?" going back to the ancient Greek philosopher Plato and the Roman poet Juvenal. Note the reverse dilemma too: accountability of the judiciary to give reasons and explain their actions is hardly controversial. But accountability by holding judges responsible for their decisions may infringe their independence, for it cannot be precluded that measures which aim to strengthen the accountability of an agent may be abused and weaken its independence. The solution of this dilemma depends on the arrangements that in practice balance the demands for judicial independence and accountability of the judiciary; see also Cappelletti (1983) and Shapiro (2002) for the tension between democracy and judicial independence. We divide the arrangements for judicial independence under two broad categories, structure and jurisdiction.

Structure

The political independence of judges increases with the following: (a) The smaller the involvement of the government in the process of their appointment and the larger the legislative majorities needed for their confirmation; independence is

even higher when judges are nominated by the judiciary itself. (b) The longer their term of service; independence is also higher when judges serve for a single term only or do not seek reappointment. (c) The greater their financial autonomy which implies that salaries and budgets cannot be reduced by discretionary acts of the executive. (d) Transparency, the obligation to explain and justify rulings, enhances the independence of judges as it increases publicly available information, influences future courses of action, obliges nonelected judges to fully justify their decisions, and discourages politicians or other interested parties to intervene in judicial outcomes. However, there is no consensus regarding the optimal degree of transparency. For example, although full disclosure has a certain intuitive appeal, keeping secret the voting record of judges may also have some advantages in the specific circumstances of supranational judicial bodies like the European Court of the EU. The court does not disclose how individual judges have voted and, contrary to the US Supreme Court, dissenting opinions are not published. This secrecy protects judges against possible retribution from governments which lost their cases at the court. (e) The more difficult it is to discipline and dismiss judges. (f) The more difficult it is for the government to overturn judicial rulings it does not like. Rulings can be overturned by introducing new legislation or changing the status and power of courts. The latter is less likely when courts are bound to follow legal precedent and when their independence is declared in the constitution which, contrary to ordinary legislation, requires supermajorities to revise.

Jurisdiction

A range of issues are examined here – see Ginsburg (2002) for a detailed discussion of the structure and organization of the judiciary. (a) Whether ordinary courts can exercise judicial review of laws, as in the decentralized US system, or only specialized constitutional courts have such rights, as in the centralized system of the European countries following the model of the Austrian legal theorist H. Kelsen. (b) Whether judicial review is concrete or abstract. Under concrete the constitutionality of a law is checked in a case which is

actually litigated in front of a court, while under abstract a law may be examined without litigation. Related to this issue is whether review is carried out before or after the promulgation of a law. US courts practice concrete *ex post* review, while the French Constitutional Court offers an example of abstract *a priori* review. Abstract and *a priori* review is not based on a real case but on a hypothetical conflict and is conducted with less information about “facts” and as such is more limited but has the advantage that it can eliminate unconstitutional legislation before it actually does any harm. (c) In general, the power of the judiciary as an independent arm rises when individuals are granted more open access to the courts and *ceteris paribus* when courts are allowed to review more legislation, since under these circumstances the hold of the executive on policy making is weaker. Note however that easy access may encourage trivial applications for annulments frustrating the exercise of the will of the majority but also increasing the judicial workload and therefore the cost of the system. (d) The ability of court rulings to “make law.” Although judiciaries do not make laws in the sense that legislatures do, insofar as they interpret legislation, their rulings become a source of law and bind future rulings, their independence is greater than otherwise. Similarly, by annulling those acts and measures that they find incompatible with the constitution and fundamental charters, courts have a form of negative lawmaking power.

Modeling the Behavior of an Independent Judiciary

The behavior of the judiciary in collective decision-making is studied by applying spatial decision models and game theory to the process of policy making. The judiciary is modeled as a rational agent pursuing an objective function defined over one or more policy variables and is pitted against the executive arm and the legislature in a sequential game; see Ferejohn and Weingast (1992), Hanssen (2000), Vanberg (2001), Rogers (2001), Tsebelis (2002), and Stephenson (2004). Introducing the judiciary in the collective choice

game typically adds the highest court as a veto player, which affects the set of feasible alternatives against the status quo. In this policy game the executive and legislative branches are not only interested in the outcomes of their own decisions but also on whether their decisions will trigger the judiciary to move and reverse such decisions.

The literature makes two key assumptions about the preferences of the judges. First, their preferences are based on “deeply internalized” notions of justice, the rule of law, and respect for legal reasoning. Second, judges would like to see their rulings implemented. However, in modeling the utility function of judges, normative objectives are not specified. To a large extent this comes from the generality of the rule of law that eludes more specific normative specification. Application of the rule of law does not necessarily imply that a “good” law is applied. The law may privilege the interests of whomever the lawmakers wish to favor. As Shapiro (2002) put it, “The rule of law requires that the state’s preferences be achieved by general rules rather than by discretionary-arbitrary-treatment of individuals” (p. 166). For example, courts of the apartheid era in South Africa were upholding the law of the land, but to the black population, they could hardly appear as neutral and independent arbiters between the interests of different races.

Empirical Studies of the Economic Effects of Judicial Independence

Application of the rule of law promotes a just society, protects individual rights, and defends citizens against predatory governments, advancing in turn economic goals. Major research breakthroughs were made with the construction of indicators of the independence and the power of the judiciary as represented by supreme courts. Empirical research has found that countries with higher degrees of judicial independence enjoy higher economic performance (Henisz 2000), greater economic and political freedom (La Porta et al. 2004), and a lower share of taxes (Tridimas 2005). Most interestingly, Feld and Voigt (2003) distinguish between *de jure* independence, as

described in legal texts setting up the supreme court of a country, and *de facto* independence which is independence of the supreme court of a country as it is actually implemented in practice, and find that only *de facto* judicial independence is conducive to growth.

Regarding the effect of the method of selecting judges, appointment or election, on judicial outcomes, the literature notes a selection effect (the ideological preferences of judges who are elected may differ from the preferences of judges who are appointed) and an incentive effect (judges seeking reelection are more sensitive to the preferences of the electorate). It is found that appointed judges are more independent than elected ones, since elected judges are more sensitive to electoral considerations and may attach greater weight to the interests of litigants from groups who are presumed to have large electoral power; see Hanssen (1999).

Informative as these findings may be, several open questions remain. In the first instance, there is the perennial problem of reverse causality, that is, richer countries can afford good judicial institutions rather than good judicial institutions leading to higher income. Second, the judiciary is approximated by the highest constitutional court and the latter is treated as a single decision taker. This ignores that in reality the judiciary comprises a hierarchy of lower and higher courts. In addition, even though the constitutional court itself is a collective body comprising several justices, subject to the well-known problems of reaching a collective decision, these problems are assumed away and the court is treated as a single decision taker. Finally, from the viewpoint of policy advice, the creation of legal institutions conducive to economic success requires long gestation periods, which may be of little comfort to a government facing pressing short-run demands for growth-promoting policies. Significantly, the results from reforming the courts of developing economies to be politically independent and introducing statutes incorporating principles and procedures of codes found in advanced western countries have been underwhelming (Carothers 2006). It appears that the same deep-lying factors of institutional failure were left intact and prevented the legal reforms to function as intended.

Independent Regulatory Authorities

Régis Lanneau

Law School, CRDP, Université de Paris Nanterre, Nanterre, France

Abstract

Independent regulatory agencies are now considered to be the sign of modern economic regulatory systems. They proliferated since the 1980s, and it is believed that they are enhancing the efficiency of regulation. In this entry, I will use law and economics to develop some rationale to explain their diffusion and emergence.

Introduction

Independent regulatory agencies represent one of the key features of modern economic regulation. They have indeed proliferated by a factor three to six between the end of the 1980s and the beginning of the 2000s in OECD countries (Jacobzone 2005; see also Pollitt and Bouckaert (2000), considering that the spread of the new public management doctrine is a key to understand the rise of agencies). Almost all OECD countries now have at least financial regulator, energy regulator, environmental agency, and telecommunication authority. Developing countries are following a similar trend since the beginning of the 1990s. In Latin America for example (but the same trend is observed in Asia), less than 45 authorities existed in 1979 (and mostly regarding financial regulation); in 2002, this number was multiplied by three to reach 138 (Jordana and Levi-Faur 2005). Independent regulators are now established in major infrastructure and economic sectors as well as social and environmental arena.

These (administrative) agencies, established in general by legislative acts, are entrusted with substantial (but variable) regulatory power – from rulemaking to adjudication and sanctions – and granted a certain level of independence (especially regarding the executive branch). This independence materializes, quite often, with fixed terms, limits regarding reappointment, guarantees against removal (a “cause” is required), a staffing structure allowing a significant place to experts (and not politicians), and collegiality at its head. This independence is never absolute since, after all, agencies are agents, acting on behalf of a principal (but since agents, they could of course pursue their own agenda, Moe 1990). Independence cannot then be the absence of accountability (see also Çetin et al. 2016; Maggetti 2012).

This “rise of the non-elected” (Vibert 2007) – and more generally of the regulatory state (Glaeser and Shleifer 2003) – is striking. It would certainly be possible to notice the influence of the European Union regarding the liberalization of certain economic sectors (an independent energy regulator was for example required) or the role of the world bank and its market-oriented

regulatory arrangement (see also Gilardi 2005). Nevertheless, the rationale (and legitimacy) for their emergence and diffusion is often consequentialist and law and economics could then be used to assess critically the validity of these rationale. If independent regulatory agencies exist, it is because they are supposed to lead to more net benefits than if the regulation was in the hands of politicians, judges, or mere dependent regulatory agencies.

In this entry, we will not provide a law and economics explanation for the rise as such of independent regulatory agencies (for development regarding this dimension, see, for example, Glaeser and Shleifer 2003; Law and Kim 2011). These explanations are of course not the only one and cannot explain, as such, the diversity of design, power, and functioning of independent regulatory agencies (see, for example, Eberlein 2000 on the absence in Germany of a sectoral regulator for electricity before the influence of the energy directives of the European Union).

Independent Regulatory Agencies as a Shield Against Interest Groups

Independent regulatory agencies are supposed to reduce the amount of political rent-seeking and its adverse effects regarding the design of policies (Shapiro 1988). Indeed, elected regulators, according to a basic economic logic, are eager to maximize their support function in order to get elected or reelected; they might not then have all the incentives to enact welfare enhancing regulations to “buy” the support of some special interest groups (Stigler 1971; Posner 1974; Peltzman 1976). Reducing or removing the political factors in regulation could then be seen as a relevant strategy. A variation around this theme can be found in Glaeser and Schleifer (2003): for these authors, regulatory agencies emerged to face the problem of large, deep-pocket firms that were able to manipulate the courts. Rent-seeking being considered in this variation at the level of courts.

This logic suffers from three problems:

First, even if the political factor is removed, the members of the regulatory agencies might have

their own agenda which are not compatible with the “public interest” (i.e., obtaining a larger budget, extending their powers) and since they are “independent,” it might be difficult to incentivize them to do the “right” thing, especially since their goals are often varied, mixed, broad, and unclear. The dilemma between independence and accountability is clear at this level. Moreover, from a strictly legal point of view, the possibility to delegate regulatory power delegate (and the extent of the delegation) to “independent” agencies is sometimes unclear (Veljanovski is considering them as “constitutional anomalies,” Veljanovski 1991) and the necessity to coordinate the agency with other institution (e.g., for enforcement).

Second, the risk of capture and rent-seeking is not to be excluded by the mere fact of independence. Indeed, agencies’ members are often experts in a field and as such have had the opportunity of repeated interaction with some of the firms they are regulating. Moreover, when they cannot be reappointed, they could wind-up in a high paying job in one of the companies they were regulating, hence incentivizing them to develop regulations not always inspired by the public interest.

Third, this logic also disregards the fact that independent agencies (and their design) could be the result of rent-seeking activities (because, for example, some industries could consider that it would be easier to pressurize this type of agency).

Take for example the Interstate Commerce Commission (ICC) spawned by the Interstate Commercial Act (ICA) of 1887. It is often considered as the first Independent regulatory agency. For Stigler (1971), railroads were able to limit of interstate trucking through their influence over the ICC. For Mullin (2000), the ICC was captured by the shippers, not the railroads. Indeed, railroads were refused to raise their rates despite the evidence of increasing input costs. Stock market evidence is pointing toward a capture by long-haul railroads at the expense of short-haul railroads (Prager 1989). Even if it is difficult to precisely identify which interest group “captured” the ICC, evidence is not showing that an “independent” regulatory agency could fully solve the problem.

Judicial review of regulatory agencies could reduce the problem, but not entirely solve it, since it is difficult to assess when the margin of discretion has been trespassed. If judicial review exists, the Glaeser and Shleifer understanding of the rise of regulatory agencies should be reinterpreted.

Independent Regulatory Agencies as a Tool to Reduce Decision-Making Costs

The idea behind this logic is simple: since the field which is regulated is perceived as a technical field (high information requirements), only experts are required to ensure an efficient regulation. Politicians or judges are, in some domains, ill-equipped to deal with the complexity and technicity required to design efficient public policies. Taking advantage of agency expertise could then make sense. This logic leads to distinguish between technical fields (choosing the best means to achieve a specific end, providing that there is a technical solution) and political – or nontechnical – fields (choosing the ends or the means when they are requiring more than a mere expertise). Such a distinction is not new but is crucial to understand the rise of independent regulatory agencies. A variation of this line of reasoning will stress the possibility to use these agencies for “blame shifting”: if the domain is unpopular, delegating it to a regulatory agency could be an easy way to avoid the “blame” which could be the results of regulations (Epstein and O’Halloran 1999).

For this distinction to make sense, it is required to have the possibility to evaluate the output of these agencies. Indeed, since the problem is supposed to be technical, deviation should be easy to identify. Nevertheless, in the real world, this is far from being the case. For example, the Treaty on the Functioning of the European Union, in its article 127, states that: “The primary objective of the European System of Central Banks (hereinafter referred to as ‘the ESCB’) shall be to maintain price stability. Without prejudice to the objective of price stability, the ESCB shall support the general economic policies in the Union with a view to contributing to the achievement of the objectives of the Union as laid down

in Article 3 of the Treaty on European Union.” Regarding the first goal, the question of the possibility to use nonconventional tools like the Outright Monetary Transaction Program has been challenged (ECJ case C-62/14). Moreover, it is difficult to identify when a European central bank’s action has been undertaken to support “the general economic policies in the EU.” In other words, when a regulatory agency is assigned more than one mission, it is extremely difficult to assess its efficiency.

Independent Regulatory Agencies as a Way to Ensure Credibility of Long-Term Policy-Commitment

The third logic – temporal inconsistencies and credibility (Majone 1996) – was first pointed regarding monetary policy – and central banks – by Kyland and Prescott in 1977. As they specified, since “economic planning is not a game against nature but, rather, a game against rational economic agents” (Kyland and Prescott 1977), the problem is to ensure the credibility of announced rules (see also Elster 2000; Alesina and Tabellini 1988). If the government retains a discretionary power, it might not stick to a policy that was announced to further other agendas. Knowing this possibility, agent will react to the announced policy depending on its perceived credibility. In other terms, even if a policy has been designed to promote public interest, this policy might be rendered ineffective by rational actors who will anticipate some future move by policy makers. When this problem exists, one solution to ensure credibility would be to delegate the regulatory power to an independent regulatory agency (see also Majone 2001; Dixit 1996) whose purpose will only be to follow some established rules, reducing the probability of instrumental and political use. The rise of independent central banks is the best illustration of this “bootstrapping” logic. A variation of that logic is stressing the possibility to use regulatory agencies to avoid present politicians to bind future politicians and reduce uncertainties (Cukierman et al. 1992 for manipulation regarding the tax system).

Once again, the problem of the possibility to identify clearly the mandate of the institution to assess if it is trespassing its power remains. The possibility of a judicial review could help but not entirely solve the problem.

Conclusion: How to Insure Accountability of Independent Regulatory Agencies?

Ensuring the accountability of these nonelected bodies remains the central question in democratic societies. If it were possible to evaluate the performance of these agencies, accountability would be easy to assess. Nevertheless, this task is rarely undertaken (Gilardi and Maggetti 2010) and probably too difficult to be a viable solution. Of course, some papers are trying to assess the impact of these regulatory agencies (quite often only indirectly, for example, Jakee and Allen 1998) but it appears difficult to disentangle regulation (and their perceived efficiency) from regulatory agencies (and their specific role as an institution of regulation). Moreover, even if some players seemed to have benefited from a regulation enacted by regulatory agencies, it remains difficult to be fully certain that it leads to negative effects (considering the difficulty to identify what would be the best achievable). As Ronald Coase advocated, it is required to compare different institutional framework not in the abstraction of a model but with an eye on what is achievable (Coase 1960).

Independence and accountability could only be ensured through a system of a new separation of power which design remains to be identified (and game theory is thus required, Hägg 1997). Among the leads and good practices, a strict adherence to the rule of due process and a perfect transparency are certainly required, so is a system of appeals of their decisions (see the entry on ► [Regulatory Impact Assessment](#)). Moreover, a special attention should be paid to agencies coordination (at the level of the European Union, a system of energy regulator coordination was mandated considering the specific dimension of the electricity and gas market. It led to the creation of the

European Regulators' Group for Electricity and Gas. Moreover, a dialogue between specialized regulatory agencies and competition authorities is also crucial for efficient regulation). Nevertheless, designing a perfect system is a Herculean task requiring information on the full constraint system (both legal and social); the best we can do is only to reduce the probability of blatantly inefficient regulations.

Informal Sector

Ozan Hatipoglu

Department of Economics, Bogazici University, Istanbul, Turkey

Abstract

I review and discuss definitions of informal sector introduced by social scientists over the last half century. I describe how informal institutions, informal markets, and their participants' activities form together the informal sector. I provide insight into the difficulties in defining informal sector from a judicial point of view. I discuss causes and consequences as well as economic costs and benefits of the informal sector. Finally, I provide a brief analysis of the existing econometrics methods in measuring its size.

Synonyms

[Hidden Economy](#); [Irregular Sector](#); [Parallel Economy](#); [Shadow Economy](#); [Underground Economy](#)

Definition

All income generating activities outside the regulatory framework of the state.

Definitions

A Brief History of Definitions

A formal meaning to informal sector (A plethora of adjectives are used to describe the informal sector in common language, e.g., shadow underground, subterranean, hidden, parallel, or irregular.) was not given until International Labor Organization (ILO) first officially introduced the term in its study of urban labor markets in developing countries (Hart 1973; Chaudhuri 2010). It was categorized as part of the urban labor force, which operates outside of formal labor regulations such as wage contracts or social security laws. The main emphasis in this conceptualization was on self-employed urban workers. ILO extended the definition of the term in 2002 to include also unregistered or unprotected labor working in formal sector firms. While this newer definition emphasizes labor markets, where most of the informal activity takes place, it is far from being authoritative or unique in its scope. In fact, a consensus on the definition of the informal sector is difficult to find because its coverage is nested in several branches of social sciences due to the multidimensional activities involved (Labor Economics, Anthropology, Sociology, Psychology, Finance, Macroeconomics, Criminology, and Statistics provide different methodological approaches to the analysis of the informal sector.) (Görxhani 2004).

Early works on informal sector have associated it with the existence of a dual labor market in developing countries (Hart 1973; De Soto 1989; Tokman 1972, 1978) and considered it as synonymous for small and self-employed. These were the key characteristics that distinguished it from formal sector where wage-employment and a well-regulated labor market existed together. This is hardly surprising given the dualistic nature of most of the world economies in the postwar and the postcolonialist era. A developed urban economy existed together with a subsistence economy based on agriculture. The rise of urban industries caused massive rural-urban migration that increased the available labor force in cities but at the same time failed to generate enough employment. The surplus labor was forced to generate its

own means of survival, and thereby it created a secondary urban employment sector that became later also an entry point for fresh immigrants (Mazumdar 1976) (Although wages in the informal sector are less than those in the formal sector in most cases, there is a wide diversity of earnings within the informal sector as ILO's Regional Employment Program, known by its Spanish acronym PREALC, reports (Tokman 1990; Mazumdar 1976; Lemieux et al. 1994)).

The dualist approach employed by researchers in treating informal sector as a separate entity received major criticism in early 1990's because of a buildup in empirical findings documenting close linkages between formal and informal sectors. Portes and Schauffler (1993) point to the existence of microproducers capable of producing with modern technology and capital accumulation, but also argue that this type of informal production is an exception in many developing countries including Latin America. Erase Harris (1990) and Sethuraman and Maldonado (1992) rejects both reject the dualist approach on the grounds that linkages between these two sectors play a greater role in explaining their formation than migration. This new strand of literature also suggests that entry to the informal sector might be due to individual choices, which are influenced by barriers to access such as heavy regulation, high taxes, or social factors.

A distinction between the legal and illegal nature of the informal work wasn't made until last two decades when authors from a variety of disciplines (Castells and Portes 1989; De Soto 1989; Feige 1990; Harding and Jenkins 1989) started to define informal sector commonly as that *all income generating activities outside the regulatory framework of the state*. This definition has now become the most widely used characterization of the informal sector in economics. Chen (2004) argues that during the 1990s, the emergence of the concepts of social capital and social networks led to questioning of the value of the concept of informality "even by its main proponents – and a significant decline in its use" (Klein 1999; Hart 1995; Portes 1994).

Since the beginning of the twenty-first century, the discussion on the definition of informal sector

has moved away from epistemological concerns to more practical issues such as how to transform informal sector concepts into instruments for statistical measurement and public policy purposes. Currently, the ILO terminology explains informality around three main notions: the *informal sector* refers to production and employment in unregistered enterprises; *informal employment* focuses on employment outside of the labor protection regulations of a given society, both in formal and informal firms; and *informal economy* covers all firms, workers, and institutions that operate outside the legal regulatory framework of society and their revenue-creating activities.

Labor Market-Based Definitions

Dual labor market theories (Doeringer and Piore 1971; Saint-Paul 1997) divide the labor market into primary and secondary or informal and illegal sectors. The primary sector consists of regular, wage jobs that are regulated and taxed and come with well-defined contracts and social security benefits. Secondary sector provides jobs with lower wages and less regulation, such as those in the service sector. Jobs in this sector are also sometimes referred to as pink-collar jobs. Informal sector consists of mostly self-employed who cannot access primary or secondary sectors. They work by themselves or create small unofficial business units in which workers are hired and transactions are made off-the-books and payments are cash-only. The final category is the illegal sector and it consists of criminal activities that generate income.

H. De Soto (1989) emphasizes the regulatory framework where the main distinction between informal and formal sector is the legal status of the activities. The legal status of the informal sector activities is a gray area in common law and a distinction is almost always necessary between what is legal and what is not. For example, a production process might be illegal in the sense that it avoids or circumvents work regulations while the output resulting from this process might be not.

Most studies on informal sector exclude criminal activity such as drug-trafficking or human trade from a labor market-based definition of the

informal sector. Unlike the criminal sector, the output in the informal sector is legal. Undeclared production of officially recorded firms is also generally considered as part of the informal sector. However, when the labor market-based definition is extended to include official firms, i.e., irregular sector, legal status of the informal sector is not straightforward. The production process in the irregular sector might be plagued with illegal procedures, such as tax evasion, avoidance of labor safety regulations, and social security fraud. Informal sector, therefore, can also be conceptualized as a market where illegal production of legal goods by unofficial firms takes place.

One can further refine this classification by distinguishing between activities that use monetary transactions versus those that use non-monetary transactions. Illegal informal activities that use monetary transaction include trade with stolen goods, drug dealing. Another common illegal informal activity is money laundering which is defined as the set of actions taken by individuals or organizations to cloak the source of funds that are created by criminal activity (Masciandar, forthcoming). Illegal informal activities that use nonmonetary transactions comprise of barter of drugs and stolen goods, theft for own use, as well as producing drugs for own use. Regular informal activities that use monetary transactions can be categorized into *tax evasion* such as unreported income from self-employment, wages, salaries, and assets from informal work and into *tax avoidance*, such as employee discounts and other benefits.

Study-Based Definitions

Since there is a substantial body of literature on informal sector descriptions, it is customary for researchers to define informal sector in accordance with the particular research question at hand. For example, studies trying to assess the size of the informal sector provide definitions of informal sector that are directly or indirectly measurable even though they might include activities that are nontaxable. Smith (1994) puts one such working definition forward as “market based production of goods and services, whether legal or illegal that escapes detection in the official

estimates of Gross Domestic Product (GDP).” Another instrumental definition with a taxability condition is provided by Schneider (2006) as “all income from monetary or barter transactions of legal goods and services that would be taxed if it were reported to tax authorities.”

Most statistical measurement studies exclude criminal activities because the magnitude of the transactions involved are very difficult to measure, but they are also broad enough to cover the diversity of ways in which the informal sector reveals itself in different countries. Studies concentrating on tax evasion or firm regulation focus on irregular sector rather than informal labor markets and take the informal sector to be a place of shadow activities of official firms.

In similar vein, the definition and the scope of the informal sector might also differ depending on whether the focus of the study is a developing or a developed country. In the former case, informal sector studies generally concentrate on labor-intensive informal work, whereas in the latter researchers have focused mostly on tax evasion and optimal regulation.

Informal Institutions, Informal Markets, Participants, and Activities

Informal institutions are governing arrangements that are created and sanctioned outside the regulatory reach of the state (Chen 2004). They are based on traditional power hierarchies or other socially accepted norms. Informal institutions as informal sector participants are more prevalent in developing countries when compared to developed countries.

Informal *markets* are organizational arenas in which factors of production and goods and services are traded.

Informal activity can refer to various informal dimensions of economic activity in an economic system. One way to describe this broad range of activities is to classify them with respect to market participants undertaking them. Individuals, small- or large-scale corporations, formal and informal institutions, financial and nonfinancial institutions, and governments all can engage in informal

activities in a variety of ways. In developed countries, formal institutions play a larger role in informal sector activities when compared to informal institutions. A corporation, for instance, can engage in informal sector activity by:

- (i) Evading taxes through hiding income from its legal activities
- (ii) Hiring informal workers
- (iii) Avoiding regulations with the aim of tax avoidance or reducing production costs to increase pretax profits
- (iv) Making hidden transactions with smaller informal firms that provide cheaper inputs in the lower end of the supply-chain.
- (v) Engaging in illegal activities such as bribery to evade taxes or to avoid workplace or environmental regulations

Individuals or households can also engage in informal activities. Individuals might work as self-employed without registration, or they might work for an informal employer such as own-account informal employers or informal own-family enterprises. Household nonmarket production is a type of informal activity that is not regulated by the state unless it is done for others. Since own household production does not create income it is generally left out from measurement studies and considered as a separate category outside the formal/informal sector divide.

Official state bodies such as governments, municipalities, or state departments can also engage in shadow activities in a variety of ways. They might extend work to informal employers without official tenders. State officials might accept bribery to facilitate procedures or to keep a blind eye on informal activities whether they are legal or not (Choi and Thum 2004; Dreher and Schneider 2006).

The formal financial institutions also engage in shadow activities in several ways. International Financial Stability Board (FSB) (2014) reports that shadow banking now accounts for a quarter of the global financial system. In many developing countries, the volume of informal finance lead by shadow banking exceeds formal finance in

terms of assets and volume of transactions. In developed countries, prior to the financial crisis of 2008, shadow banking mostly referred to legal structures that are used by official banks to keep complicated and risky securities off their balance sheets. With increased regulation on bank operations, informal banking now has become an independent sector and its definition is now extended as “credit intermediation involving entities and activities outside the regular banking system.”

Where formal banks have access to ample funds but are unable to control the use of credit, informal lenders can prevent nondiligent behavior but often lack the needed capital.

Formal Versus Informal: Causes and Consequences

In economics literature, taxes, social security burden, increased regulation, forced reduction in weekly working time, earlier retirement, unemployment, decline of civic virtue, and loyalty towards public institutions are counted among the main reasons for the existence of the informal sector (Frey and Hannelore 1983). Psychological studies offer factors such as tax morale and perceived fairness of the tax system and micro-sociological studies offer exclusion and other social barriers to entry as main causes of the informal sector.

In empirical studies, researchers have looked at the correlates of informal sector size by controlling other factors. Common significant factors found in these studies reflect the generally accepted aforementioned reasons, but some puzzles still exist (Hatipoglu and Ozbek (2011) report that a high informal sector size is associated with little redistribution and lower taxes especially in developing countries).

Monitoring and enforcement in the irregular sector are costly efforts for the regulator due to the high number of qualified personnel hours required. Stronger enforcement and heavier regulations can result statistically in less number of firms evading taxes, and a higher tax collection rate, but at the same time it may lead incumbent and newcomer firms to engage more in informal

activities thereby increasing informal sector size and reducing tax revenues.

The same argument applies to informal labor markets. When faced with higher taxes, individuals might opt out from formal sector and switch to informal sector to protect their after-tax income. As a result, the formal sector might shrink in size as well as in productivity as more skilled people switch to informal sector. Depending on its workforce's skill distribution, a country might have a large informal sector with plenty of skilled jobs or relatively small informal sector with relatively high overall unemployment. This trade-off is analyzed by Ihrig and Moe (2004) that shows how enforcement policies and tax rates interact to determine the size of the informal sector. They find even small changes in tax rates can significantly affect the size of informal employment. On the contrary, increased enforcement has negligible effect on informal employment. Their results suggest that modest reductions in tax rates combined with modest punishment for tax evasion are more effective than strong enforcement alone. The size of the informal sector and the level of redistribution is the result of the joint effects of distributional factors and how lucrative the informal sector is.

Many authors argue that reducing costs of entry to formal sector can reduce the size of the informal sector and improve labor market performance. Increasing enforcement may also reduce informality but can have negative effects on unemployment and welfare such that there is a trade-off between lower informal employment and higher unemployment rate. However, the trade-off disappears when one prefers policies that aim at reducing the costs of being formal, as opposed to policies that increase the costs of being informal.

Many scholars have emphasized the costs of operating in both sectors (Loayza 1996; De Soto 1989, Tokman 1990; Sarte 2000; Portes et al 1989). In the formal sector, in addition to having to pay direct or indirect taxes, formal firms need to comply with guidelines such as labor safety, environmental protection, consumer safety and quality control, as well as administrative procedures such as registration, and other

bureaucratic paper work. Wage regulations and project delays stemming from contract negotiations with organized unions also increase formal sector's operating costs. Whereas in the informal sector, there are costs to getting caught since the informal firm is penalized if detected. The major cost or lack of benefit associated with the informal sector is, however, that its participants cannot take advantage of state-provided public goods such as the police, the judicial system, as well as of business-related resources such as those provided by official trade organizations.

Working in the formal sector requires a minimum set of skills and entry costs. Guilds and business associations require their members to pay annual fees and comply with regulations. In return, individuals have access to resources and infrastructure that can help to improve their productivity. Depending on the tax burden, the intensity of regulations in the formal sector and wages in the informal sector, formally trained individuals such as doctors and lawyers might also choose to work in the informal sector.

Informal Sector: Costs Versus Benefits

The existence of the informal sector can be thought of as the expression of negative sentiments of individuals who are overburdened by the state and choose the exit option. If, in fact, the informal sector is caused by the burden of regulation, then an increase in informal sector size can cause a vicious cycle by eroding the tax base and thereby causing a further increase in tax rates (Olson 1982). A large informal sector size can create problems for both the voters and the policy-makers in taking the optimal decisions because official indicators on unemployment, income, and consumption become misleading.

Depending on how lucrative the informal sector is and how productive the formal workers are, people may choose to work in the informal sector to accommodate for their low levels of productivity. This in turns leads to less output in the formal sector with little to redistribute. This is consistent with the observation that the existence of a large informal sector coincides with less redistribution

in many developing countries. Hatipoglu and Ozbek (2011) show that informal sector may act as a redistributive mechanism in countries where the democratic rule is skewed towards the rich. Increasing the wages in the informal sector vis-à-vis the earnings in the formal sector leads to a decrease in subsidies and an increase in the informal sector size, which suggests that nontaxation is an indirect form of subsidizing incomes and that informal sector acts as an alternative way of redistribution.

Informal sector can also operate in a way to reduce the burden of taxation further by creating new jobs for the low skilled who otherwise would be dependent on the government. Empirical evidence from ILO and World Bank studies show that most of new jobs in the developing world over the past 15–20 years have been created in the informal sector. The main reasons are rapid growth of the labor force, insufficient formal sector job creation, and lack of social safety nets (Chen 2004; Blunch et al. 2001: 10; ILO 1972). In addition, most of the income created in informal sector is immediately spent in the formal sector; thus increased informal activity can also help the formal sector to grow.

Measuring the Size of the Informal Sector

Measurement of the informal sector size is one of the central themes of the informal sector literature. Correct measurement of the informal sector size is important for a variety of reasons. Firstly, it can identify the exact amount of distortion caused by informal sector activities in major national statistics such as GDP allowing both voters and policymakers to make more informed decisions. Secondly, causes and consequences of the existence of informal activities can be easier to identify and policy prescriptions can be made more efficiently.

Currently, there are a number of alternative estimation methodologies that differ in their approach in tackling the unobservable nature of the informal sector (See Frey and Hannelore (1984), Schneider (2006) and Schneider and

Enste (2000) for a more detailed presentation and critique of the available estimation methods).

Direct Methods

Direct approaches collect data directly from participants either through *microsurveys* or use the available data collected through *tax audits*. Since direct approaches depend on the respondents' willingness to comply it suffers from a statistical measurement error called sample bias. People who chose to respond are less likely to engage in informal activities and if they do, they tend to underreport those activities. This makes estimating the range of informal activities as well as translating it into monetary terms difficult. On the other hand, this approach provides detailed information about the structure of the informal sector that is difficult to obtain using indirect approaches.

In the *survey method*, a sample population thought to represent the actual population of a country is chosen to be respondents. The answers are statistically extended to the whole population. The *tax audit* method, on the other hand, measures the discrepancy between incomes declared for taxation and incomes measured by selective checks. This approach provides more precise estimates of the informal activities that selected respondents undertake, but it also suffers from a sample bias problem, since respondents are not selected randomly but based on their previous tax record and likelihood to evade taxes. Finally, except hidden income, most informal sector activities are poorly captured by this method.

There are two common deficiencies of the aforementioned direct approaches. Firstly, they only provide point estimates in time and do not provide information on how informal sector evolves over time in terms of size. Secondly, they provide also poor estimates of the composition of informal sector.

Indirect Methods

Indirect or *indicator* approaches use aggregate macroeconomic data or other "indicators" to infer about the size of the informal sector. These indicators are thought to capture the traces left by the informal sector activities in national statistics. One such trace is the *discrepancy between the*

official and the actual labor force. A decline in labor force participation is an indicator for increased activity in the informal sector. The main disadvantage of this method is that changes to labor participation rates might be due to other reasons than increased informal activity. Another indicator of the informal activity is the discrepancy *between GNP measures based on expenditure and income*. Since GNP based on expenditure and income approach should be equal, any discrepancy can signal the size of the informal sector. National statisticians are likely to minimize this discrepancy because they are caused by measurement error.

Currency demand approach assumes that informal sector transactions are mostly handled in cash, and therefore excess money holdings above what money demand regressions would predict can capture the size of the informal sector. It is one of the most commonly used methods in OECD countries. Since not all transactions are paid in cash, this method might underestimate the size of the informal sector. Another weakness of this method is that the rise in currency demand might be due to the slowdown in demand deposits instead of a rise in informal activity. This method also assumes the same velocity for money in both sectors, which might not be true (See Tanzi (1983) for an introduction and Thomas (1999) and Schneider (2002) for criticisms of the method. Giles (1999) and Bhattacharya (1999) address some of those criticisms.).

Physical input method assumes all kinds of production use a general-purpose, measurable input such as electricity. Since economic activity and electricity consumption are highly correlated in data, one can infer about the size of the informal sector by comparing the measured GDP and imputed GDP calculated using the measured inputs. The main criticism against this method is that some informal activities do not use electricity at all, e.g., personal services and many activities use energy sources other than electricity, e.g., oil and natural gas. Finally, the efficiency of electricity usage might change over time such that estimations over time become inconsistent.

Transactions method uses Fisher's quantity equation that relates the volume of transactions

to the velocity of money, prices, and money supply Feige (1986). Official GDP is subtracted from the total volume of transactions implied by the equation. Here, assumptions have to be made about the velocity of money being constant in both sectors as well as the existence of a base year with no informal sector, both of which might fail to hold.

Econometric Modeling Methods

This approach treats the informal sector as an unobservable variable and uses structural equation modeling to control for the causal relations between the informal sector size and its causes (burden of taxation, regulation, etc.) as well as the informal sector size and its effects (money demand, labor force participation rate, etc.). Schneider (2004), for example, uses dynamic multiple indicators multiple causes (DYMIMIC) method to estimate the size of the shadow economies around the world. This method provides only relative estimates; therefore results have to be combined with absolute measures from currency approach to compute absolute measures for all countries.

Informal Sector Sizes in the World

There are many studies which estimate the size of the informal sector for large sets of countries using aforementioned methods. A detailed survey is beyond the scope of this article. Interested readers can check Zilberfarb (1986), Lacko (1996), Tanzi (1999), Thomas (1999), Schneider and Enste (2000), Chatterjee et al. (2006), and Schneider (2009) among others in chronological order.

Conclusion and Future Directions

Works on the informal sector have concentrated on its definition, measurement, causes and consequences, as well as its links to other spheres in law and economics. Latest economic realities such as free trade and market friendly reforms seem to have contributed significantly to the growing prominence of the informal sector in economic

activities. The developmental history of third world countries as well as boom-bust cycles of the developed world have radically changed perceptions about the relationship between the formal and informal sectors and their roles in economic development. Researchers from a wide variety of backgrounds continue to explore links between the informal sector and other fields such as law, trade, finance, political economy, growth, and income distribution.

Within this realm, the role of informal finance has significantly grown during the last half-decade and especially after the financial crisis of 2008. One can expect to see more studies on the role of regulations in the financial industry in shadow banking as well as in other types of informal finance. Further contributions aside mainstream economics can be expected from network analysis, new institutional economics, micro-finance, legal pluralism studies, as well as Foucauldian studies on political economy.

Abstract

While contracts are often useful devices for achieving commitment, they can be imperfect devices for doing so when contract breach is unverifiable by third parties or unobservable by the parties themselves. This contribution focuses on the law and economics literature which explains particular features of contract law on the basis of problems of non-verifiability and non-observability. An example is the legal system's use of weaker or no sanctions for contract breach of specific types of contracts, like employment and marriage contracts. It also includes the use of the non-verifiability problem for the evaluation of the desirability of particular legal duties, such as the duty to renegotiate contracts when circumstances change unexpectedly.

Synonyms

Non-observability; Non-verifiability

Introduction

A contract is an exchange of goods and services. However, an exchange does not necessarily

require a contract. A contract is a legal instrument that puts legal pressure on the actions that parties have agreed to take at various times. Parties want their contracts to be enforced by courts to avoid the danger of opportunistic behavior. The danger of opportunism arises when performance of contractual obligations is nonsimultaneous. For then, in the absence of legal enforcement (and assuming pure self-interested behavior, no repeat play, no reputation sanction, and no taste for fairness), the last performing party has an incentive to opportunistically withhold or change his performance obligation. The problem of opportunistic behavior can be solved by drafting a contract that specifies the actions that parties are supposed to take at various times and that makes the nonperforming party subject to legal sanctions. If a party breaches the contract without a good excuse, the legal system has several choices. It can either oblige her to perform the contract as agreed (specific performance) or oblige her to pay compensation instead (damages). For example, a buyer of goods or services will often write down in a contract, sometimes in great detail, the seller's obligations. When the seller fails to satisfy these obligations, he breaches the contracts. The seller sues for damages. If the court decides that the seller did not satisfy his obligations, it will award damages. While contracts are often useful for achieving commitment, they can be imperfect devices for doing so for several reasons (Hermalin et al. 2007). First, the use of contracts to assure commitment is difficult, when due to uncertainty parties lack the information to specify the terms of their exchange in advance. This problem has been the focus of the relational contract literature (Goetz and Scott 1981). A legal requirement to force parties to specify their contracts in more detail in advance is considered not to be a good solution, as it may lead to a party's bankruptcy. Vertical integration and third-party governance have been proposed as possible solutions (Williamson 1975; Klein et al. 1978). Second, when the damages from breach are relatively low compared to the enforcement costs, enforcement may be incredible. Damage multipliers have been proposed as a possible solution in case the probability of a suit is low (Craswell 1996).

But even if legal commitment has been established and the means for its enforcement are available, a contract may be an imperfect method for assuring commitment (i) when breach of a contractual obligation cannot be verified by a third party, like a judge (non-verifiability problem), and (ii) when breach is unobservable by the parties themselves (non-observability problem). There is a standard distinction in economic theory between information that parties can observe and information that is verifiable by a third party. The distinction is drawn because the costs of proving to a third party (e.g., courts) that a particular state of the world existed or a particular action was taken can exceed the gains.

Unverifiable Breach

Even if a contract party can determine that there has been a breach, she may be unable to demonstrate that fact to a third-party enforcer at reasonable cost. For example, an employer may notice that an employee who promised to work hard is shirking his duties. Still, it may be difficult for an employer to prove in court that performance was substandard. The employer cannot act on observable but non-verifiable evidence. In many cases the most important element in the success of a business is cooperative effort, which depends heavily on attitude and morale. Yet these are often the most difficult elements to explain to an outsider (Epstein 1995). The problem of non-verifiability is particularly pressing when a debtor does not commit to achieve a specific result (“obligation de résultat”), but instead commits to provide his best efforts to realize a result (“an obligation de moyens”). In the latter case, the duties undertaken are directed toward a result, but the debtor is only forced to deploy certain methods, thereby meeting the required standard of behavior, such as best efforts. Creditors often have a hard time to prove with verifiable facts that a debtor did not use his best efforts. The simple fact that the result was not achieved is not a useful proxy for low effort, since the bad result may also be due to bad luck. For example, if a lawyer is hired to work in the best interest of his client, it

may be difficult to show that the quality of his pleadings is low – the fact that he lost the case may be due to factors beyond his control. The contract itself may sometimes require a debtor to prove with verifiable facts that sufficient steps were taken with a view to achieving a desirable result, but this system cannot capture all appropriate actions. Eric Posner (2000) points out that the use of expectation damages for breach of contract is problematic in cases in which the debtor’s ability to perform is dependent on non-verifiable actions of the other contracting party. A contract which forces the debtor to pay expectation damages in case she fails to perform gives good incentives to the debtor to perform the contract. But suppose that the creditor is expected to take actions which make it more likely that the debtor is able to perform, but these actions are non-verifiable. Expectation damages would then give the wrong incentives because they would reward the creditor who fails to provide best efforts.

Parties sometimes do contract on the basis of observable but unverifiable information. Such contracts are, in the economic literature, said to be “implicit” or self-enforcing. They help parties to coordinate their affairs and are performed as long as coordination is mutually beneficial (or as long as reputational concerns compel compliance). An implicit self-enforcing contract is one where opportunistic behavior is prevented by the threat of termination rather than by the threat of litigation (Klein 1980). It is left to the judgment of parties concerned to determine whether or not there has been a violation of the agreement. No third party intervenes to determine whether a violation has taken place or to estimate the damages that result from such violation. If one party violates the terms, then the only recourse of the other party is to terminate the agreement after he discovers the violation. Both parties continue to adhere to an agreement if and only if each gains more from adherence to, rather than violation of, its terms (Telser 1980). People keep promises because the prospective gains from doing so exceed the prospective losses. Still, the circumstances under which the threat of termination would be a sufficient deterrent are quite severe:

the value of the contract to both parties must either be expected to continue indefinitely or have a substantial positive probability of continuing in all future states (Rosen 1984). Otherwise, there are well-known tendencies toward opportunism as the end-period approaches, and the contract is no longer self-enforcing. This problem has been discussed in economics under the name of the “last-period” problem.

Unobservable Breach

Breach is unobservable when the beneficiary of a contractual duty is unable to determine whether the promise has been kept or broken. For example, an employer may be unable to determine whether an employee has kept his promise to treat customers in a friendly manner when the employee works at a distant location. Output-based pay instead of a fixed wage may be a way to give incentives to increase the quality of the input, but is not a viable solution in case the agent is risk averse. The challenge is then to design a “mixed contract” so that there are incentives to perform well, but without burdening the agent with too much risk. The multitasking problem is a further complication of output-based pay (Holmstrom and Milgrom 1991). If payment is made dependent on the performance of one task, the agent’s incentives to perform well with respect to other tasks would be severely impeded. Given the incentives and risk problems with output-based pay, many employees receive fixed wages instead. With monitoring being less than perfect, employees are to some extent free to decide how hard they will work. What motivates them to work hard when wages are fixed? What motivates them to do more than the observable and verifiable minimum standard of performance, like showing up for work during working hours? Intrinsic motivation, altruism, and an agent’s identification with the principal’s goals become important in this context. De Geest et al. (2001) have pointed out that the use of expectation damages for contract breach is problematic in cases in which intrinsic motivation is important for contract performance, since it may destroy such incentives.

Why the Legal System May Sometimes Use Weak or No Sanctions for Contract Breach

In general contract law, the standard damage measure for contract breach is the expectation measure. This measure awards compensation for both the reliance expenses (“negative contract interest”) and the expected profits (the “positive contract interest”). The threat of having to pay expectation damages in case of contract breach is a rather heavy dose of legal pressure on contractual obligations. Still, law and economics scholarship considers it as the optimal sanction because it assures that breach only occurs when it is efficient. But for specific types of contracts, modern legal systems adopt much weaker or no sanctions for contract breach. According to the US employment-at-will doctrine, an employment relationship without a definite duration can be freely terminated. Both the employer and the employee have the right to abrogate the relationship at any time, for any reason, without notice or compensation. Parties have no ground to challenge the termination in court. The implication is that employment is “voluntary,” meaning that parties perform only because they want it, not because otherwise they would be sanctioned for contract breach. Of course the absence of *legal* pressure to cooperate does not mean the absence of any pressure. *Informal* pressure may exist to trade, for example, because a party would otherwise lose a deferred benefit. Many European dismissal laws equally put little legal pressure on employment parties to cooperate with each other. In Europe, many employment relationships can be terminated without having to show just cause, provided that reasonable notice is given. Except in the limited cases where there is an abuse of rights or bad faith termination, parties have no ground to challenge the termination in court. An employee who quits early does not have to compensate the employer for the loss of expectancy, but only has to pay an amount of money in lieu of notice. Why is not more legal pressure put on employment parties to stay in their relationship? Dari-Mattiacci and De Geest (2005) explain the legal system’s use of weak sanction on the basis of

the problem of non-verifiability. In order for the legal system to put legal pressure on employment parties to perform, courts would have to find out in case of employment termination which one of the parties is responsible for the failure of the employment relationship and subject that party to legal sanctions. But courts have substantial problems in verifying who was (more) responsible for the failed employment relationship. Did the employee perform poorly? Did the employer promise a more interesting and more challenging job than he offered in reality? Was one of the parties constantly unfriendly and perhaps even responsible for an unpleasant working atmosphere? These facts may be very difficult for a third party to figure out. Of course courts could easily verify which one of the parties took the initiative for the separation and sanction the initiative taker accordingly. However, if sanctions were made to depend on whether the separation is a quit or a layoff, then the distinction can quickly become blurred (Milgrom and Roberts 1992). An employer can often make an employee's life so miserable at work that he or she just has to quit, or an employee can misbehave so badly that the employer sees no choice but to fire the offender, and yet third parties cannot tell who is blamed. Such a sanctioning system will induce parties to play a "you-quit-first game." Each party will try to push the other one to quit first in order to avoid being the one who gets sanctioned. What is the outcome of this game? Who has the best chance to win a you-quit-first game?: (a) the party with the highest ability to generate negative externalities (destroying work or making life unpleasant) and (b) the party who performs poorly. If party A keeps his promises but party B breaches, staying in the relationship is least attractive for party A. As a consequence, and somewhat paradoxically, the non-breacher is most likely to quit first. In order to avoid that the "wrong" party is sanctioned for the unsuccessful employment relationship, legal systems should be reluctant to sanction contract breach when there is a low degree of verifiability. If third parties don't know who the true breacher is, it may be better not to sanction anyone in order to avoid the risk that the innocent party is the one that effectively gets the sanction. Dari-Mattiacci and De Geest (2005)

also apply their framework to divorce laws, which regulate the sanctions in case of marriage contract termination. Here too the courts have difficulties in finding out which party could have done more to prevent marriage failure. Parties to a marriage contract promise to love and respect each other, but finding out which party failed first to provide best efforts to keep the obligation is very difficult. Instead, courts could use easily verifiable proxies, such as who was the party who first quit the house or started a new relationship, and sanction that party accordingly. But again this would lead to parties playing a you-quit-first game, and – as predicted by game theory – it is not necessarily the true breacher who quits first. Therefore, it may be better for the legal system not to sanction contract breach in case of divorce. A no-fault divorce system corresponds with this insight. Under no-fault divorce, neither spouse is required to prove "fault" or marital misconduct on the part of the other to obtain a divorce, and marital misconduct cannot be used to achieve a division of property favorable to the "innocent" spouse.

Should There Be a Duty to Renegotiate Contracts in Case of Unexpected Circumstances?

The 2009 Draft Common Frame of Reference (DCFR) is a European model code envisioned as a collection of "best solutions" for definitions, terminology, and substantive rules in European private law. DCFR III – 1:110 (3)(d) states that if the performance of a contractual obligation becomes so onerous because of an exceptional change of circumstances that it would be manifestly unjust to hold the debtor to the obligation, a court may vary the obligation or terminate the obligation, but only if the debtor has attempted, reasonably and in good faith, to achieve by negotiation a reasonable and equitable adjustment of the terms regulating the obligation. It has been seriously doubted whether there should be a legal duty to negotiate in good faith (De Geest 2010). There is no exact standard available to define the conduct that is required by the parties, and for courts it may be very hard to find out which party negotiated in good faith.

Because of this “non-verifiability,” courts may tend to look at signals, i.e., easily observable facts that are believed to be associated with the negative behavior they want to discourage. Two such observable facts are the amount of time spent to negotiating and which party stopped negotiating first. Yet these signals may unintentionally create a you-quit-first game. Each party may try to make the other party leave the negotiation table first, so that the other one is held responsible for the failure of the negotiations. A legal duty to renegotiate is likely to cause delay and strategic behavior. Moreover, a legal duty is not necessary since contracting parties have private incentives to renegotiate their contract because in that way, they can save litigation costs.

Information Disclosure

Mika Pajarinen

The Research Institute of the Finnish Economy (ETLA), Helsinki, Finland

Abstract

This essay discusses information disclosure, i.e., making company related information accessible to interested parties, in regard to economic literature. The two main fields in which information disclosure is dealt with in this context are corporate finance and innovations. Short notes on other contexts in economics are also made. The essay excludes the descriptions of formal procedures and legal aspects of disclosing information.

Definition

To make (company related) information accessible to interested parties.

Information Disclosure in Corporate Finance

In corporate finance literature information disclosure relates closely to investment and growth opportunities. Firms whose financing needs exceed their internal resources may suffer from financial market imperfections due to asymmetric information and incentive problems between corporate insiders and outside investors (see, e.g., Berger and Udell 1998; Hubbard 1998; Petersen and Rajan 1994). The informational opacity of a firm may reduce the availability of external finance to the firm because the more opaque the firm the more scope there is for opportunistic

behavior by the firm's insiders (more moral hazard) and the harder it is for investors to determine the quality of the firm (more adverse selection). This may lead to higher interest rates demanded by investors and higher risk investment projects chosen by a firm than in a situation in which all relevant information on firm's financial status has been made accessible to potential investors. A conventional wisdom in the contemporary corporate finance literature argues the informational opacity of firms is in relation to firms' age and size. Recent entrants with short track record suffer more from the informational opacity than incumbent firms. Smaller firms are also typically more opaque than larger firms because their minimum requirements for information disclosure, e.g., in financial statements, are more scant than in larger, especially in the listed, firms.

Firms can reduce their informational opacity by voluntarily disclosing high quality information on their business activities over and above mandated disclosure. High quality disclosure is especially important for firms with lucrative growth prospects because for them standard disclosure is of too low quality. It is of too low quality in the sense that mandated disclosure often alleviates information asymmetry only to a limited extent. This kind of higher quality disclosure incurs, however, costs to firms. There can be many types of costs. Direct costs arise from producing and credibly disclosing information. In addition to more comprehensive accounting processes, this may include, for instance, acquiring prestigious auditors and the premiums charged by them. Furthermore, indirect costs can arise from various reasons, such as the pro-competitive effects of disclosure (Bhattacharya and Chiesa 1995; Healy and Palepu 2001). Disclosure may also reduce the incentives of outside investors to acquire information (Boot and Thakor 2001). Firms have thus to balance with the costs of high quality disclosure with returns of growth opportunities. Titman and Trueman (1986) show in a formal model that the firms that choose high quality disclosure are, in equilibrium, those with favorable information about the firm's future and its growth opportunities.

Information disclosure in corporate finance is related also to the interactions of the insiders of

firms, i.e., corporate governance system. Hermalin and Weisbach (2012) argue that more transparent disclosure policies can in fact aggravate agency problems between managers and shareholders and increase firms' costs due to higher rates of executives' turnover and compensation demanded by them. Efforts to be more transparent can lead to a situation where managers are more reluctant to increase firm value in the long run but rather boost short-term investments and other actions that affect reported figures sooner at the expense of longer term (riskier) value creation investments, such as R&D.

Information Disclosure and Innovations

Besides corporate finance, information disclosure relates in economic literature also to generation of innovations. When a firm has made an innovation, it can basically choose to keep the innovation secret or apply for a patent. If the firm applies for the patent, it discloses the discovery of invention and provides information about it to the public. In addition, the patent applicant is obliged to reveal all prior art that may be relevant to the patentability of the applicant's invention. This includes disclosing existing technological information on both documentary sources, such as patents and publications, and nondocumentary sources such as things known or used publicly, which is used to determine if an invention is novel and involves an inventive step (for further details on patenting process, see, e.g., European Patent Office's www-pages <http://www.epo.org>).

When a firm is granted a patent on an invention, it gets a temporary monopoly right in exchange for disclosure. The monopoly right lasts normally 10 years. After the period of patent protection, the invention is freely available to competitors and other potential users. Other parties than the inventor can also utilize the patented innovation during the life of the patent by licensing and other arrangement facilitating a market for technological exchange. Social costs of disclosing the invention by patenting arise if this technological exchange does not perform well. In this case, patented inventions may hold up subsequent research on related inventions and

may generate substantial transaction costs from costly legal challenges about possible infringement (see Gallini 2007 for a more detailed discussion of the role of disclosure in the case of patenting and Griliches 1990 for a review of patents as innovation and economic indicators).

Information Disclosure in Other Contexts

Besides corporate finance and innovations, the term information disclosure is used for instance in consumer economics in regard to how transparent information firms are willing to reveal on their products to consumers (see, e.g., Ghosh and Galbreth 2013; Polinsky and Shavell 2012).

Furthermore, in the field of competition analysis, information disclosure is used in the context of its influence on competition in the field of interest (see, e.g., Arya and Mittendorf 2013; Feltham et al. 1992; Hayes and Lundholm 1996). More detailed information disclosure reveals more data to competitors and can potentially weaken disclosing firm's position in the market. On the other hand, an incumbent firm may strategically choose to disclose some information to prevent new entries in the market. In addition to competing firms, individual firm's disclosures may have spillover effects also in non-competing firms by revealing information on technological trends, governance arrangements, best policy practices, etc.

Synonyms

[Creativity](#); [Novelty](#)

Definition

The process of devising a new idea or thing or improving an existing idea or thing (Sandefur 2008). Innovation is also defined as “the implementation of a new or significantly improved product (good or service), or process, a new marketing method, or a new organizational method in business practices, workplace organization or external relations.” It differentiates between four types of innovations, namely, “product Innovation,” “process Innovation,” “marketing Innovation,” and “organizational Innovation” (OSLO Manual, OECD 2007).

The Term Innovation

Meaning of the Term

The introduction of something new; a new idea, device, or method (Latin: innovatio: renovation, replacement, change, novelty). Innovation in a general sense is understood as renovation and redesign of divisions and parts of economy, science or society, in specific functioning models or behavior patterns in relation to an existing system (economically or socially). Innovation is understood to be an improvement of existing procedures, materials, or devices or a better match to changed requirements of functionality. Innovation has to be distinguished from invention and diffusion. Invention focuses on the mental process of creating a new idea. The emphasis is lying in the moment of creation, the birth of something, that is brought into the material world. In contrast to the term invention, innovation requires also the aspect of the new idea being applied or performed in a way that matters within the context of the innovation. An innovation has to introduce relevant changes on the applied level. Not every invention is necessarily an innovation. In comparison to sustaining innovations, innovations with a high relevance of change are called *disruptive innovations* (see “Clayton M. Christensen: Disruptive Innovation”). Diffusion describes the following process of spreading and transferring the applied invention in the market. Historically the term has been used in French since the thirteenth century in its general

meaning, in English it was recorded since the fifteenth century. Up to the twentieth century, the term had a specific meaning merely in botanic sciences and legal procedures. After World War II, the term has spread through reception of macro-economic theories on the international level.

Innovation as a Term of Economics

Innovation as a term of economics has been introduced by the Austrian-American economist *Joseph Schumpeter* in his *Theory of innovations* first published in 1912. Innovation as a concept of implementation of new products, processes, or management ideas is strongly connected to Schumpeter’s idea of creative destruction. Creative destruction occurs, when innovations make existing products and services obsolete, thus freeing resources to be employed and used elsewhere. So, creative destruction leads to greater efficiency. The creative entrepreneur profits from return of investment by temporary monopoly through innovation instead of profiting from exploitation of price differences. According to Schumpeter, the process of innovation consists of three parts: invention (the creation of the new idea), the innovation itself (implementation of the invention), and the market diffusion (production and sale). A product or process is called innovative only if there is market diffusion, that makes the difference between the mere invention and the innovation.

Innovation as a Legal Term

Innovation is not regarded a technical legal term. Until 2014 there has not been a legal definition of innovation, although the frequency of the term in statutory European and national law is steadily increasing. European Directive 2014/24/EU on public procurement defines innovation in Art. 2 (22) as “the implementation of a new or significantly improved product, service or process, including but not limited to production, building or construction processes, a new marketing method, or a new organizational method in business practices, workplace organization or external relations inter alia with the purpose of helping to solve societal challenges or to support the Europe 2020 strategy for smart, sustainable and inclusive growth;”

The term innovation has been introduced by the European Commission already in 2010 within the programmatic term *Innovation Union*, which is part of the strategy Europe 2020. Innovation in this sense means more than being innovative. “The EU initiative [Innovation Union](#) focuses Europe’s efforts – and its cooperation with non-EU countries – on the big challenges of our time: energy, food security, climate change and our ageing population. It uses public sector intervention to stimulate the private sector and remove bottlenecks which prevent ideas from reaching the market – including lack of finance, fragmented research systems and markets, under-use of public procurement for innovation and slow standard-setting.” (Communication of the Commission [2010](#)) Here innovation is more of an action program following specific political aims. Whereas innovation as an economic concept describes the economic success of innovative products through efficiency in some relation.

Innovation as a Term in Social Sciences

What Schumpeter developed for economics, Friedrich August von Hayek developed in the political theory of the “Open Society,” where he stressed the importance of innovation for social values. Hayek believes in the existence of an order in society. “It would be no exaggeration to say that social theory begins with - and has an object only because of - the discovery that there exist orderly structures which are the product of the action of many men but are not the result of human design” (Hayek [1944](#)). He assumes that planned orders are inferior and will not produce prosperity. Still prosperity requires some kind of regulation by man, as the rule of law, to prevent innovation being steered in a parasitic direction. “Natural selection operates on mutations, making the path of natural selection unpredictable, regardless of how well we understand the underlying principles” (Hayek [1944](#)). To Hayek, social and cultural evolutions are much the same: driven by innovation, fashion, and various shocks that “mutate” people’s plans in unpredictable ways with unpredictable results. The system may be more or less logical. And by no means predictable.

Concept of Innovation in Economics

Joseph Schumpeter: Creative Destruction

Schumpeter defines innovation as a process of changes focused on the creation of something new. The combination of various economic factors in a new, “innovative” way has an impact on the economy and the society on the whole. According to Schumpeter, the process of technological change has three levels: invention (the creation of a new idea), innovation (setting up the elements for the implementation of the invention), and market diffusion. Innovation has an overall positive connotation. But as every human activity innovation has costs as well as benefits. Instead of bringing relieve, creating wealth and power, innovations can also disrupt the status quo. Schumpeter calls the process of creative destruction the process by which innovation causes resources to be set free and therefore introduced the term creative destruction. Creative destruction occurs when innovation makes production processes obsolete and frees resources that can be employed elsewhere, thus increasing efficiency. Creative destruction has always been feared as source of unemployment. The term creative destruction is sometimes also known as Schumpeter’s gale, which Schumpeter derived from Karl Marx and integrated it into his theory of economic innovation. According to Schumpeter, the “gale of creative destruction” describes the “process of industrial mutation that incessantly revolutionizes the economic structure from within, incessantly destroying the old one, incessantly creating a new one” (Schumpeter [1939](#)). In the earlier work of Marx, the idea of creative destruction or annihilation implies not only that capitalism destroys and reconfigures previous economic orders. It must also ceaselessly devalue existing wealth (e.g., through war, dereliction or economic crises) in order to clear the ground for the creation of new wealth. Schumpeter believes in the existence of an economic equilibrium, whereas Marx defines the boom as a consequence of a depression. The motor of innovation according to Schumpeter is the position of monopoly, which the creative entrepreneur will seize by introducing an innovation.

Clayton M. Christensen: Disruptive Innovation

Not every innovation is of the same kind: there are sustaining innovations made by incremental research, aiming at keeping up technologically with competing firms. Most inventions produce sustaining innovation. Disruptive innovation describes a process, where innovation creates a new market and value network that will eventually disrupt an already existing market and replace existing products. It is more the business model that creates the disruptive impact, than the existence of one high technology invention. Disruptive innovation refers rather to the evolution of a product or service than to a product or service at a certain point. Harvard Business School economist Clayton M. Christensen introduced the term disruptive technologies in his article *Disruptive Technologies: Catching the Wave* (1995) with his cowriter Joseph Bower and described the term further in *The Innovator's Dilemma*. Later he replaced the term by disruptive innovation when he recognized that few technologies are intrinsically disruptive or sustaining, but that it is rather the business model enabled by the technology that has a disruptive character. The evolution from a technological focus to a business modeling focus is a central part of his concept.

Christensen said: "The technological changes that damage established companies are usually not radically new or difficult from a technological point of view. They do, however, have two important characteristics: First, they typically present a different package of performance attributes—ones that, at least at the outset, are not valued by existing customers. Second, the performance attributes that existing customers do value improve at such a rapid rate that the new technology can later invade those established markets" (Christensen 1995). Christensen differentiates between low-end disruption and new-market disruption. The first is targeting at customers that do not need the full performance value; the second is targeting at new customer groups whose needs have not been served by existing incumbents. Christensen's theory of disruptive innovation had a strong influence on business and his book was chosen for one of the most important books in economics. Eventually the term disruptive innovation was said to

be overused and to have become a cliché among people, partly because they do not understand Christensen's concept.

Functionality of Law for Innovation

Innovation as a process is not intrinsically a legal matter. But innovation requires an atmosphere, where values and rights indispensable for innovation have to be protected by the law. Law may be used, to protect existing values in a society, but not to create them. In the same time law has by means of regulations to avoid "parasitic" directions to mention Hayek, if innovation shall create prosperity. "A primary role of law and (when necessary) legislation is to narrow people's options so as to limit opportunities to get rich at other people's expense. So long as the rule of law can internalize external cost and thereby steer innovation in mutually beneficial rather than parasitic directions, an evolving order will be an order of rising prosperity." Law therefore has at least two functions for innovation: protecting the basis for its requirements and steering it by regulation. Law can open up the field for innovation, support enabling innovators to act, set incentives, steer and regulate. The functionality of law therefore is more of an instrument. The innovation process describes different stages of economic development that require legal regulation in various areas of law. As innovation regularly implies inventions or creation of know-how innovation is above all strongly connected to the law of intellectual property. To allow something new to emerge and to keep the position of monopoly created by the implementation of an invention, innovation requires the legal regulation of rights that embody inventions or know-how and can be used as tradable carrier of that right. So, intellectual property law can be regarded as the legal core of innovation (but not the basis). Neighboring subjects as the law of employees' invention and contract law (licensing contracts, research & development contracts) contribute significantly to innovation too. Innovation requires confidentiality, protection of trade secrets, exclusivity and protection against competitors. But these are only

legal topics on the surface of innovation. Innovation requires not only new ideas but also entrepreneurship and capital. In legal terms, innovation therefore requires basic rights and freedoms, as the freedom to do research and to work in an open academic environment with scientific methods. Capital needs to be stable and mobile.

But law may also be used to trigger or facilitate innovation. So legal regulations on funding R & D, enabling public-private partnerships in R & D, company law that offers easy to handle formats for companies and facilitates fast registering, tax law privileging insurance companies offering risk capital to start ups, labor law regulations that enable flexibility in hiring people, or low rates of courts and offices in patent matters may have strong impact on innovation. Innovation is not one legal field, but rather a cross-cutting issue.

Legal Basis of Innovation - the Legal Side of Entrepreneurship

Entrepreneurship is understood as the ability and willingness to act creative. The ability to act creative requires a spirit of individualism and the development of scientific methods in a society. The law can support this spirit and capacities by protecting the basic rights and freedoms: freedom of scientific research, freedom of movement, freedom of establishment, and others. Innovation needs to create its own requirements. Innovation may be a rule of interpretation on the level of constitutional law when it comes to fundamental understanding and interpretation of laws and jurisdiction. The relation between innovation and stability has to be solved in favor of the development of constitutional law, rather than preservation and persistence. In federal states, procedural means to compensate differences in federal judiciary by examining decisions on the level of constitutional law regarding their congruence, as well as the introduction of actions for natural persons on the constitutional level are also ways to open law to innovation. Freedom in business means to provide for competition. In Hayek's words, "the law should not only recognize the principle of private property and freedom of contract, but the legal system should also give a precise definition

of these two principles in a way that promotes competition" (Hayek 1944). With the fast growth of high-tech markets the phenomenon of monopolies and dominant market positions have to be observed closely and if necessary regulated to conserve competition. But innovation has changed structures of markets too: "market shares move faster, barriers to entry the market tend to be much lower, and natural monopolies leave as fast as they come" (Schrepel 2014, 216). Antitrust law therefore has to be updated to these new market mechanisms. "A paradox clearly appears on this point. Indeed, very few persons argue that antitrust should promote perfect competition. However, not to take every single aspects of innovation into account, – for instance, by not including disruptive and permissionless innovations in our analyses – has for consequence to indirectly promote this model of perfect competition. For the reason, it is time to hold innovation as real antitrust standard" (Schrepel 2014, 216).

Confidentiality

Innovation exploits the fact that a product, material, service, or business model is new to the rest of the market and therefore enables a monopoly. Once the invention is to become an innovation, it has to be filed as a patent and implemented in the market as a product. To uphold the monopoly as long as possible, the entrepreneur needs to protect himself against competitors by a ban to use his invention, a patent, by keeping most of his technological competence secret, by defining know-how as trade secret of his business. In all cases, you need confidentiality, which usually is created by non-disclosure agreements, material transfer agreements, and obligations of confidentiality in labor contracts.

Confidentiality has to be limited in time and relevance. An invention kept secret absolutely can hardly have an innovative impact. Sometimes the position of a monopolist can be upheld by suppressing innovation that could disrupt the incumbent product. On the long run though, it is difficult to suppress innovation entirely. So on the

one hand confidentiality is required to create monopoly; on the other hand, there will be no profit without implementation, which means the invention has to be made public to some extent. As innovation implies inventions and invention imply novelty, you need a protection of your research and development results before you file them as a patent. As a result non-disclosure agreements regulate a graded confidentiality, limited to the relevant topics, limited in time and people, who need to know. They oblige their partners to keep information defined as confidential secret and not to use it in any other business relation. Limitation of the obligation here is fundamental, without it, entrepreneurs may end up in an information blockade that eventually destroys business opportunities. Attempts to regulate confidentiality on a European level have not been successful. As non-disclosure agreements are used to create trustful relations between partners, it might be better not to make them obsolete by legal regulation.

Intellectual Property Law

Intellectual property law describes legal rights designed to enable technology transfer and doing business with IP. Patents, utility models, designs, registered marks, as well as trade secrets and know-how are means to protect the innovation against competitors and to keep the monopolistic position as long as possible. The patent is used for the protection of inventions. In the global market, it was very important to have a common understanding and a similar regulation of the patent in the different countries. With the Patent Cooperation Treaty, the Paris Convention for the protection of Industrial property rights, the foundation of the World Intellectual Property Organization there is a basis for economical exploitation of inventions in the global market. A patent is the right to forbid anyone to use the invention that is filed for a patent in the geographical area of the patent for a maximum of 20 years. Global Players need to register in all countries, where they intend to use the patent, which is, where they produce and sell a product, based on the patent. This can result in high costs, depending on the number of countries the patent should be registered for. The patent is

the strongest intellectual property right, especially compared to know-how or utility models. An essential difference between regulations on patents between European and US law is the patentability of business models in US Law, whereas under European Law business models can only be protected by means of protecting its designs or registered marks used by the business model. In Europe, a patent can only be granted for the solution of technical problems. Considering that the so-called platform businesses profit more from their business model, than from a specific high technology invention, the scope of application of European patents should be rethought. The European initiative to introduce a common European Patent and a corresponding judiciary has been stopped for the time being – not by Brexit negotiations, but by court actions challenging the judicial independence of European Patent authorities, currently discussed vigorously.

Law as Stimulation and Facilitation

Law can stimulate innovation by facilitation of legal processes or introduction of completely new legal forms. For example, the Innovation Partnership, a special form of procurement procedure in European public procurement law, introduced in 2014, is a specific procurement procedure with the aim of developing an innovative product or service and then acquiring the resulting services. Due to the special European procurement law for the member states, the legal institution also works in its procurement law which enables flexibility within the European market. A characteristic of the procedure is a respective two-stage of award procedure and the subsequent contract model. Many public procurement regulations on European level as well as on national levels are directed to the promotion of innovation.

Legal Requirements during the Process of Innovation

The process of innovation usually describes the development starting with research and

ending with the revenue gained after commercialization of the innovative product, service, or business model. Depending on the affiliation of authors, the process of innovation may concentrate on the first part and be called Technology Transfer process or concentrate on the commercialization and start up business. Among the plenty and various models for the innovation process, most of them can be divided into three larger phases, subdivided by different steps.

Phase 1: Conception/invention/knowledge phase:

This includes idea generation and evaluation, pre-disclosure, and invention disclosure assessment protection. On the legal side this requires potentially non-disclosure agreements, labor contracts for scientists with paragraphs on intellectual property and confidentiality, invention disclosures, patent or utility filings, patent investigation, and more.

Phase 2: In the second phase, the implementation or adaption phase, the invention made in phase 1 is developed into a product, a prototype, or even more a pilot series, ready for being tested. On the legal side this is accompanied by product development agreements with the company that intend to develop a product. This can either be an existing company or a start-up. In the latter case, the process is completed by financing. Usually the different processes overlap. Once a pilot series has been concluded successfully, innovation is ready for production in phase 3.

Phase 3: It starts with the licensee agreement, production, and continues with the market launch, eventually aiming at market penetration. Legally the step from phase 2 to 3 is enormous, because the law treats production very different from research and development. Liability of manufacturer, quality management, technical data sheets, higher insurance rates, different general conditions are only some of the legal aspects, production and sale require. This is a reason, why usually production is located in a different legal entity to keep the higher risks separate from research and development.

Impact of Innovation on the Development of Law. New Legal Questions?

Law can influence innovation, as well as innovation has an impact on the development of law. Digitalization, artificial intelligence, and information technologies let us rediscover old problems in a new form, but sometimes also raise new questions. The relation between these innovative technological fields and law, the question of regulation of technology is a cross-section field: liability, traffic law, data protection law, and criminal law. Digitalization requires data protection and raises the question of information privacy, especially when digitalization is introduced in the public sector for e-government, as introduced by the European Union with the eGovernment action plan 2016–2020 and e-government laws on the national level as the German law in 2013. As mentioned before, on one hand law will have to facilitate innovation by enabling mobility of citizens and businesses by cross-border and facilitating digital interaction between administrations and citizens/businesses for high-quality public services. On the other hand, it will have to limit the amount of personal data to be collected and protect citizens against misuse of personal data.

Data protection law in Europe is criticized for fulfilling its purpose only imperfectly. In wide ranges, it is still based on the data protection concept of the 1970s, when central data storage on mainframes, limited storage capacities, and a relatively small circle of – mostly government – data processors were characteristic. Only slowly legislation can keep up with the needs of technical development. The European Union started a general data protection reform and issued the General Data Protection Regulation in 2016, according to which the Data Protection Directive of 1995 expires. On the national level, data protection law, e.g., in Germany, is considered “over-regulated, fragmented, confusing and contradictory” (Roßnagel et al. 2001).

Digitalization requires the regulation of issues raised by the increasing use of automated and autonomous devices. Especially the fact that we

allow machines to make decisions for us raises significant problems of liability, responsibility, and the nature of legal personality. For the self-driving car law, for example, we will have to decide, which risks will be carried by manufacturer's responsibility and what will lie within the driver's liability. The solution of dilemmas in emergency situations, to be decided by machines, may not be solvable by law, but rather by ethics, sociology of technics, and "interdisciplinary methods to be developed" (Valentiner 2016).

Summary

Innovation is the process of devising a new idea or thing or improving an existing idea or thing. In contrast to the term invention, innovation requires also the aspect of the new idea being applied or performed in a way that matters within the context of the innovation. Innovation as a term of economics has been introduced by *Joseph Schumpeter* and is strongly connected to his idea of creative destruction. Clayton Christensen coined the term destructive innovation. His theories had a strong influence on business administration. Innovation requires entrepreneurship and capital. The function of law is to protect the basis for innovation and to regulate and steer it. Digitalization, information technologies, and artificial intelligence are challenges to the law. After decades of rising numbers of legal regulations, innovation could take us to the limits of law.

Institutional Change

Christopher Kingston
 Amherst College, Amherst, MA, USA

Definition

Institutions are durable; that is precisely what makes them meaningful and important. But institutions also sometimes change. This entry compares a variety of theoretical approaches to understanding the process of institutional change. Some authors treat institutional change as a centralized, collective-choice process in which rules are explicitly specified by a collective political entity, such as the community or “the state,” and individuals and organizations engage in collective action, conflict, and bargaining to try to change these rules for their own benefit. Others emphasize the “spontaneous” emergence of institutions as an evolutionary process, in which new institutional forms periodically emerge and undergo some kind of decentralized selection process as they compete against alternative institutions. Still others combine elements of evolution and design. We differentiate a variety of approaches to the interaction between formal and informal rules and explore the path-dependent nature of institutional change. We also discuss recent theories based on the “equilibrium view” of institutions, which emphasizes that the constraints that motivate individual behavior are ultimately derived from expectations about the behavior of other actors in various contingencies. In maximizing

their welfare subject to these constraints, agents choose strategies which, in the aggregate, give rise to expectations which reinforce the constraints on everyone else, so the effective “rules” of the game emerge endogenously as equilibrium outcomes, and exploring institutional change involves explaining changes in equilibrium behavior.

Theorizing Institutional Change

The scholarly literature on institutional change is voluminous, but diffuse and eclectic, plagued by ambiguity about the meaning of commonly used terms including even the meaning of the term “institutions” itself. In this entry, adapted from a broader paper on the subject (Kingston and Caballero 2009), I attempt to map out the major theoretical approaches to institutional change and to highlight the main possibilities that an empirical researcher might consider.

Before we can discuss institutional change, we must define what we mean by “institutions.” Unfortunately, the appropriate definition is far from a settled issue, and the different definitions used by different authors naturally influence their views of institutional change. Many authors, however, adopt some variant of Douglass North’s view that institutions “are the rules of the game in a society or more formally, are the humanly devised constraints that shape human interaction” and that they “reduce uncertainty by providing a structure to everyday life” (North 1990: 3). Fundamentally, then, institutions are viewed as “rules” that are “humanly devised.”

There are many different kinds of “rules”; however, most authors follow North in distinguishing between “formal” rules such as laws and constitutions and “informal” constraints such as conventions and norms. Even this basic distinction is far from straightforward. The term “formal” is often taken to mean that the rules are made explicit or written down, particularly if they are enforced by the state, whereas “informal” rules are implicit; another interpretation is that formal rules are enforced by actors with specialized roles, whereas informal codes of behavior are

enforced collectively by the members of the relevant group. “Informal constraints,” as North notes, “defy, for the most part, neat specification” (North 1990: 36) but include “socially sanctioned norms of behavior” as well as “extensions, elaborations, and modifications of formal rules” and “internally enforced standards of conduct” (North 1990: 40).

But while social norms enforced by a community, conventions, and internalized ethical codes such as religious beliefs can all be viewed as informal constraints, they are distinct phenomena which may change in different ways and may have different short-run and long-run effects on the broader pattern of institutional change. This ambiguity has created considerable confusion about the nature of informal constraints and their interaction with formal rules. For example, some authors have regarded informal constraints as essentially immutable, or that they change only slowly, but there have also been episodes when at least some kinds of informal constraints, such as social norms, can change rapidly.

For the moment, then, let us treat institutions as the (formal and informal) “rules of the game” in a society; we will discuss an alternative definition later. How do these rules change? Two main kinds of processes emerge from the literature. Some authors view institutional change as the outcome of purposeful (centralized) design, either by a single individual (such as when a king issues a royal decree) or by many individuals or groups interacting to create or change rules through some kind of collective-choice or political process. Other authors envision institutional change as a more gradual, evolutionary (decentralized) process, frequently involving competition among alternative institutional forms. In empirical settings, aspects of both kinds of processes are often present, and the question becomes how they interact. This raises a host of conceptual issues, including how we should think about the interaction between formal rules and informal constraints, the role of politics and collective action, the nature of “competition” between different institutional forms, the role of bounded rationality and learning, the exogenous and

endogenous causes of institutional change, and the role of history and the potential for path dependence.

Politics and Collective Choice

Many authors treat institutional change as a centralized, collective-choice process in which rules are explicitly specified by a collective political entity, such as the community or the state, and individuals and organizations engage in collective action, conflict, and bargaining to try to change these rules for their own benefit.

Ostrom (2005), for example, envisions a multilayer nested hierarchy of rules: “operational rules” that govern day-to-day interactions, “collective-choice rules” (rules for choosing operational rules), and “constitutional rules” (rules for choosing collective-choice rules). In order to analyze how rules are formed at one level, Ostrom temporarily treats the higher levels of rules as fixed (*ibid.*: 61). For example, when “operational rules” are being chosen, constitutional and collective-choice rules are treated for the moment as exogenous.

The impetus for institutional change arises when some group or individual perceives an opportunity to change rules in a way that benefits them. This could be because of an exogenous change in underlying parameters that change the perceived costs and benefits from an institutional change – for example, a change in technology or relative prices. But the cause might also be endogenous if, say, people’s choices under one set of rules gradually lead to changes in parameter values that alter the costs and benefits of institutional change and thereby undermine current institutions. For example, Acemoglu and Robinson (2005) argue that after 1500, some European countries experienced a substantial growth in Atlantic trade which increased the political power of merchant groups. The growing strength of merchant groups in these countries led to institutional changes that constrained the power of monarchs and led to the development of institutions that were more conducive to economic growth.

The process of institutional change, in Ostrom's framework, is this: each individual calculates their expected costs and benefits from an institutional change, and if a "minimum coalition" necessary to effect change agrees to it, the change is enacted. What constitutes a "minimum coalition" is determined by the higher-level rules; for example, in a dictatorship, the dictator alone might constitute a winning coalition; in a democracy, a majority would constitute a winning coalition. The outcome therefore depends on how decision-makers perceive the likely effects of a change in rules and on whether those that desire change are able to bring it about or whether those that expect to lose by the change are able to block it under the higher-level rules which frame the political (rule-making) contest. Powerful groups may be able to block beneficial change or impose inefficient change. Of course, some kind of compromise or partial institutional change is also a possible outcome.

Free-rider problems can impede collective action to change formal rules. Voting, protesting, joining political associations, and learning about the impact of potential policies may all be individually nonrational actions, even if the individual cares deeply about the result. Leaders can play a key role by offering a "vision": attempting to shift their supporters' perceptions of the costs of the existing system or the feasibility and desirability of some proposed alternative. Whether they seek wealth or power, or are driven by ethical or philosophical values, the fundamental challenge that leaders must overcome in order to achieve institutional change is that of winning support and overcoming collective action problems among their potential supporters.

The role of political actors, such as judges and politicians, can be envisaged in a variety of ways. For some purposes, politicians might be viewed as simply reflecting the interests of particular groups, so that the political process remains essentially a battleground in which interest groups compete to mold formal rules to their own advantage. Other theories, however, give political actors a more autonomous role. For example, in Kantor's (1998) framework, groups of constituents lobby politicians to change formal rules, and the

politicians have incentives to be responsive to their constituents' demands. However, the politicians also have their own objectives and face other political and constitutional constraints. Which of these perspectives on the role of political actors is most appropriate will depend on the configuration of interest groups and the political structure in a given context.

Another important set of barriers to institutional change arises when the beneficiaries of a reform cannot credibly commit to compensate the losers because of the lack of an external authority to enforce intertemporal bargains. These problems are exacerbated when there is uncertainty or when there are a large number of parties to a negotiation. Acemoglu and Robinson (2006) highlight the importance of commitment problems as a cause of institutional change. In their theory, disenfranchised groups can use violence to force constitutional change (seize power), but because of collective action problems, they can only organize violence during rare (and exogenous) moments of crisis. Violence is destructive, so in a crisis, there is an opportunity for a mutually beneficial bargain in which the incumbent ruling groups would agree to carry out reforms, in exchange for which the disenfranchised groups would refrain from carrying out a revolution. However, the disenfranchised groups' opportunity to use force is fleeting, and the ruling groups cannot credibly commit themselves to honor their commitments to reform after the moment of crisis is passed. Therefore, a revolution to effect institutional change, though destructive and costly, may be the only way for currently disenfranchised groups to credibly constrain the policy choices of future governments.

Many authors note that institutional change a "path-dependent" process – that is, the institutions observed at any point in time, may in part be a function not just of current technology but also of precedent institutions and technologies (David 1994, 2007). Frequently, existing institutions create groups with a vested interest in preserving the status quo, which can impede institutional change and enable inefficient institutions to persist. More generally, the resources, physical and human capital, skills, technologies, and

organizations accumulated under one set of institutions can gradually alter the set of technologically feasible institutions and thereby affect future institutional development. Furthermore, even when these impediments are overcome, institutional change is usually incremental since it is often easier to achieve consensus on small adjustments than to effect major changes to existing rules.

There are also important behavioral aspects to the issue. The way people process information, solve problems, and learn may be important for understanding institutional inertia and change. For example, people may systematically misperceive opportunities in a complex and changing environment or may be unaware of potentially beneficial institutional changes until the new institutions are “invented.” North (2005) presents a framework in which economic actors have “mental models” which reflect their understanding of the world and which they use to evaluate the desirability of particular rule changes. Over time, as they learn about the world, they revise their mental models and may alter their perceptions of the effects of alternative rules and of the set of possible alternatives, providing an impetus for institutional change. This suggests that a key to understanding institutional change is an understanding of how people learn and revise their “mental models.” Ongoing research in cognitive psychology and behavioral economics offers the promise of deepening our understanding of many aspects of institutional change.

Although viewing institutional change as the outcome of a deliberate, collective-choice process of rule creation yields many insights, it also leaves several important questions unanswered. In particular, it has difficulty explaining why, in many cases, formal rules are ignored or fail to produce their intended outcome. A key reason for this difficulty is the prevalence of “informal” constraints that are not a product of deliberate design and often vaguely defined. To clarify, let us distinguish three types of “informal rules.”

First, the term “informal” is sometimes simply used to indicate that the rules are not written down or are not enforced by the state. A related

interpretation emphasizes the importance of actors with specialized roles in enforcing formal rules (Milgrom et al. 1990).

Second, informal constraints are sometimes viewed as ethical codes or moral “norms” which are internalized and directly reflected in players’ preferences.

Third, an important category of “informal rules” includes conventions – viewed as self-enforcing solutions to multiplayer coordination games (Sugden 1989) – and “social norms” which use a multilateral reputation mechanism and a credible threat of punishment to generate trust among members of a community (see, e.g., Kandori 1992; Greif 2006). Of course, these constraints may eventually come to be followed without rational evaluation and socially experienced as moral, ideological, or “cultural” rather than purely strategic constraints. However, if all others are following such rules, then even fully rational strategic players may also be induced to follow them. This is crucial because, even if most people follow the norm without rational evaluation, it is unlikely that a norm could evolve or survive if a rational mutant could achieve a higher payoff by deviating from it.

The second and third categories of informal rules (moral norms, conventions, and social norms) do, sometimes, change over time, but they do not fit easily into the collective-choice models because they generally evolve in a decentralized, “spontaneous” manner, rather than being deliberately designed and agreed to. This may be a serious shortcoming in some contexts because the evolution of informal rules is frequently an important part of the story of institutional change. Internalized moral codes, for example, may to some extent evolve to be compatible with prevailing formal rules, but they can also impact how formal rules change. For example, certain proposed rules may not be adopted because they are perceived as “unfair.” This is another channel through which “history matters.” Similarly, it is not uncommon for informal “rules” to originate as voluntary patterns of behavior that develop within a community and are later “formalized.” Many aspects of commercial law, for example, derived from the codification of

merchant's practices which had evolved spontaneously (Milgrom et al. 1990; Kingston 2007).

Evolutionary Theories of Institutional Change

A large body of literature treats institutional change as an evolutionary process, in which new institutional forms periodically emerge and undergo some kind of decentralized selection process as they compete against alternative institutions. In the evolutionary theories, new rules or behaviors (mutations) may emerge from deliberate human actions (including learning, imitation, and experimentation), or they may develop "spontaneously" from the uncoordinated choices of many individuals. The key difference between evolutionary theories and the collective-choice theories discussed in the previous section has to do with the decentralized selection process which determines which rules ultimately become widely adopted. Those institutions that prove successful spread, by imitation or replication, while unsuccessful institutions die out. As a result, overall institutional change occurs "spontaneously," through the uncoordinated choices of many agents, rather than via a single, collective-choice or political mechanism.

Sometimes, an evolutionary model of institutional change is implicit. Williamson (2000)'s "Transactions cost economics," for example, *assumes* that the sets of rules ("governance structures") that can most efficiently govern any particular transaction (those that "minimize transactions costs") are those that will be observed. Implicitly, this rests on an assumption that competitive pressure would weed out inefficient forms of organization, as originally suggested by Alchian (1950), because more efficient organizational forms will yield higher profits and will therefore survive and be imitated. So, for example, if a change in production technology renders existing institutions inefficient, competitive pressures ensure that a new configuration of optimal institutions will emerge. This approach is an example of "functionalist" reasoning: to

explain the attributes of an institution, we need to only ask what function it serves.

Although a functionalist approach can successfully explain many aspects of observed institutions, it does best in situations in which competition among institutional forms can plausibly operate to weed out inefficient rules and leads to a unique, optimal equilibrium. It has difficulty explaining why countries with similar technologies may use different institutions to govern apparently similar transactions, why inefficient institutions often seem to persist, or why less successful societies often fail to adopt the institutional structure of more successful ones.

The essence of these difficulties is that evolutionary processes frequently exhibit multiple equilibria. For example, credit cards are widely used by consumers because many merchants accept them for payment; and they are widely accepted because they are widely used. The resulting equilibrium is associated with a set of formal rules (credit card agreements), norms, and behaviors (carrying little cash), but we can easily envisage many other alternative institutional configurations, any of which, once established, would generate stable expectations and behavior within the context of a different set of "rules." That, is there may be multiple possible sets of self-enforcing rules ("conventions"), and there is no guarantee that the most efficient will be observed (Sugden 1989).

The possibility of multiple evolutionarily stable equilibria has two important, closely related consequences. First, observed institutions are not necessarily "efficient." And second, institutional change may exhibit "path dependence," in the sense that initial conditions and historical events can have a lasting impact on the institutions which are ultimately observed. For example, an institutional structure which was previously optimal might become sub-optimal as circumstances change, but without a coordinating device, such as legislation or the appearance of a "political entrepreneur," to engineer a change in the rules, the economy might remain stuck in the (now) sub-optimal equilibrium. Young (1996) uses an evolutionary framework to argue that historical accidents could lead to the selection of particular

conventions and argues that in the long run, the pattern of institutional change will follow a “punctuated equilibrium” process in which rapid switches between conventions are interspersed with long periods of stability.

Brousseau and Raynaud (2011) argue that many institutional arrangements begin as “private” local experiments, in which participation is voluntary, but that over time, through competition for adherents, economies of scale, and network effects, some (not necessarily optimal) institutions spread and emerge as “winners” and become “solidified” and formalized as part of the institutional environment, while participation in them becomes increasingly widespread and mandatory. Thus, they argue, some kinds of informal institutions can gradually “climb the ladder” and metamorphose into formal and permanent rules.

Blending Evolution and Design

Both the evolutionary and design-based approaches to understanding institutional change are useful in particular settings, but both are incomplete. Theories which view institutional change as the outcome of a centralized collective-choice process have difficulty explaining changes in informal constraints (such as social norms) that evolve in a decentralized manner, while evolutionary theories tend to neglect the role of collective action and the political process. This is not meant as a criticism of these theories: they have been developed to study a variety of different situations, and the assumptions and conclusions naturally reflect these differences. But in many real-world settings, both evolutionary processes and intentional design are at work, and it will often be difficult to cleanly separate the two. For example, gradual underlying changes in parameters, beliefs, or knowledge, which result from the spontaneous evolution of existing institutions over time, may give rise to deliberate attempts to design and implement new institutions; and following such attempts, competition or other evolutionary processes may subsequently play a role in determining whether particular institutional innovations survive and spread.

The question therefore naturally arises as to how to integrate these theories. To a large extent, this turns on the interaction between formal rules, which are generally deliberately designed (although there may also be evolutionary processes underlying their creation, as in the case of the common law), and informal rules, which are “much more impervious to deliberate policies” (North 1990: 6) and therefore (usually) evolve spontaneously.

Here, again, it is useful to begin with North (1990)’s seminal contribution. In North’s account, formal rules change through a political process as a result of deliberate (though boundedly rational) actions by organizations and individual entrepreneurs, while informal rules evolve alongside, and as extensions of, formal rules. Informal rules play a key role in institutional change because they change slowly and cannot be changed deliberately. Following a change of formal rules, therefore, the informal rules which “had gradually evolved as extensions of previous formal rules” (ibid.: 91) survive the change, so that the result “tends to be a restructuring of the overall constraints – in both directions – to produce a new equilibrium that is far less revolutionary” (ibid.: 91). Essentially then, formal rules occupy the driving role in institutional change; informal constraints apply the brakes.

In general, there are multiple equilibria and no guarantee of an efficient outcome (North 1990: 80–81: 136). The process of institutional change is also path-dependent because individuals learn, organizations develop, and ideologies form in the context of a particular set of formal and informal rules (1990, chapter 9). These organizations then may attempt to change the formal rules to their benefit, and over time this in turn may (indirectly) affect the informal rules.

Roland (2004) distinguishes between “fast-moving” (political) institutions (akin to formal rules), which can be changed quickly and deliberately via the centralized political process, and “slow-moving” (cultural) institutions (akin to informal rules), which change slowly because change is continuous, evolutionary, and decentralized. He outlines his view of institutional change by analogy: tectonic pressures along fault

lines (changes in slow-moving institutions) build up continuously but slowly and then suddenly provoke an “earthquake” that causes abrupt and substantial changes in fast-moving institutions (i.e., formal rules). Thus, Roland’s theory is, in a sense, the inverse of North’s, in that changes in informal rules, rather than formal rules, are the main drivers of institutional change.

The “Equilibrium View” of Institutions

A growing body of recent research shifts the focus by identifying institutions with equilibrium patterns of behavior rather than the “rules” that induce the behavior (Greif and Kingston 2011). This “equilibrium perspective” emphasizes that the constraints that motivate individual behavior are ultimately derived from expectations about the behavior of other actors in various contingencies. In maximizing their welfare subject to these constraints, agents choose strategies which, in the aggregate, and perhaps unintentionally, give rise to expectations which reinforce the constraints on everyone else. Of course, these expectations may be summarized in the form of formal and informal “rules.” But the constraints that motivate behavior – the “true” rules of the game – emerge as endogenous equilibrium outcomes, reflecting a socially constructed reality.

From the equilibrium perspective, institutional change becomes fundamentally not about changing rules, but about changing expectations; the essential goal of introducing new “rules” is to help players coordinate on one of the many possible equilibria by coordinating their beliefs about each other’s expected behavior both on and off the path of play. In equilibrium, however, it is ultimately these behavioral expectations, rather than the prescriptive content of the rules themselves, that motivate compliance. And, for a variety of reasons, it is possible that an attempt to introduce new “rules” may fail to change these expectations and equilibrium patterns of behavior or may change them in unanticipated ways. The process of institutional change is consequential precisely because there are typically multiple equilibria.

A rule “forbidding” some behavior, for example, will be effective only if people generally expect others (including those charged with enforcing the rule) to act in a way which makes it effective.

A formal rule making one player a judge, president, or police officer does not change that player’s set of physically feasible actions, but it *may* systematically alter people’s perceptions about how those actions are to be interpreted and how other players will respond: *if* the rule is effective, then by virtue of her role, the judge can take actions and give orders which would not be followed if she were an ordinary citizen. In order for the rules to be effective, the behavior specified by the “rules” – including that of the “enforcers” of the rules – must correspond to an equilibrium in the underlying “game of nature.”

Theories that define institutions as rules tend to obscure these possibilities because they consider the enforcement of rules separately from their content; they cannot explain why some rules are followed and others are not. For example, the legal speed limit on highways in Massachusetts is 65 miles per hour, but this limit is widely ignored. This is not to say that there are no “rules,” however. Most cars travel around 70 mph and are (almost) never pulled over at this speed, whereas cars traveling at 80 mph sometimes are (and those traveling at 90 mph frequently are). What accounts for the difference between the behavior specified by the “formal rule” and the behavior actually observed? Asserting that there is an “informal rule” specifying the observed behavior is unsatisfactory; it merely assumes away what we would most like to explain. The equilibrium perspective offers a more satisfactory explanation: drivers’ and police officers’ behaviors constitute an overall equilibrium based on a broadly shared set of behavioral expectations. By making the “enforcement” of rules endogenous to the analysis, this approach enables the treatment of “formal” and “informal” constraints in a unified manner.

Both deliberate, centralized and evolutionary, decentralized institutional changes are compatible with the equilibrium view. Exogenous parameter shifts such as changes in technology or

preferences can disrupt an equilibrium, leading individuals and organizations to try to change the “formal rules” in order to achieve a coordinated shift of many players’ beliefs about each others’ strategies. Previous institutions also provide focal points which can affect equilibrium selection in novel situations (Sugden 1989). Alternatively, gradual changes in parameters might cause gradual adjustments to expectations and behavior. Since the formal rules remain unchanged, this kind of institutional change could, of course, be interpreted as changing “informal rules,” but that merely labels the phenomenon without explaining it. Fundamentally, what is changing is a pattern of equilibrium behavior.

Greif and Laitin (2004) refer to parameters which are exogenous in the short run but which gradually change as a result of the play of the game as “quasi-parameters.” Changes in quasi-parameters may either broaden the range of situations in which the existing pattern of behavior (institution) is an equilibrium or may undermine the existing institution, leading to an “institutional disequilibrium” and an impetus for institutional change. Institutional change, in this view, is highly path-dependent; as Greif and Laitin emphasize, knowledge, resource ownership, wealth distribution, and other “quasi-parameters” can all be affected by past institutions and affect both the future institutional choice set (the set of feasible equilibria) and the choice of institutions within that set.

Conclusion

The appropriate model for studying institutional change is largely a matter of context. For situations in which competition will tend to weed out inefficient institutional forms, functionalist explanations such as the “transaction cost” model are likely to be useful for explaining observed institutions. In situations in which changes in formal rules occur within a stable political context, and have relatively predictable effects on behavior, treating institutional change as an outcome of collective action and political maneuvering may be more suitable. However, this approach cannot

explain why some formal rules become effective and others do not and tend to neglect the role of informal rules. The equilibrium view of institutions provides a more complete theory by treating both informal and formal rules, and their enforcement, within an integrated framework, and is therefore useful as a broad conceptual framework for understanding institutional change. However, it may introduce unnecessary complexity in the many real-world cases in which formal rules are relatively straightforward and effectively enforced.

Institutional Complementarity

Fabio Landini¹ and Ugo Pagano^{2,3}

¹LUISS University, Rome, Italy

²University of Siena, Siena, Italy

³Central European University, Budapest, Hungary

Abstract

Institutional complementarity refers to situation of interdependence among institutions. The present article presents a formal representation of institutional complementarity and discusses several economic applications of this concept.

Definition

Even if several definitions have been proposed in the literature (Crouch et al. 2005) they share the idea that institutional complementarity refers to situations of interdependence among institutions. Institutional complementarity is frequently used to explain the degree of institutional diversity that can be observed across and within socioeconomic system and its consequences on economic performance. In particular, the concept of institutional complementarity has been used to illustrate why institutions are resistant to change and why introducing new institutions into a system often leads to unintended, sometimes suboptimal, consequences.

Institutional Complementarity

The canonical formal representation of the concept of institutional complementarity is due to Aoki (2001) and relies on the theory of supermodular games developed by Milgrom and Roberts (1990). The basic structure of the model takes the following form.

Let us consider a setting with two institutional domains, A and B , and two sets of agents, C and D that do not directly interact with each other. Nevertheless, an institution implemented in one domain parametrically affects the consequences of the actions taken in the other domain. For instance, A can be associated with the type of ownership structure prevailing in a given country and B with the structure of labor rights. For simplicity, we assume that the technological and natural environment is constant.

Suppose that the agents in domain A can choose a rule from two alternative options: A^1 and A^2 ; similarly, agents in domain B can choose a rule from either B^1 or B^2 . For simplicity, let us assume that all agents in each domain have an identical payoff function $u_i = u(i \in C)$ or $v_j = v(j \in D)$ defined on binary choice sets of their own, either $\{A^1, A^2\}$ or $\{B^1, B^2\}$, with another sets as the set of parameters. We say that an (endogenous) “rule” is institutionalized in a

domain when it is implemented as an equilibrium choice of agents in the relevant domains.

Suppose that the following conditions hold:

$$\begin{aligned} u(A^1; B^1) - u(A^2; B^1) \\ \geq u(A^1; B^2) - u(A^2; B^2) \end{aligned} \quad (1)$$

$$\begin{aligned} v(B^2; A^2) - v(B^1; A^2) \\ \geq v(B^2; A^1) - v(B^1; A^1) \end{aligned} \quad (2)$$

for all i and j . The latter are the so-called supermodular (complementarity) conditions. Equation 1 implies that the “incremental” benefit for the agents in A from choosing A^1 rather than A^2 increases as their institutional environment in B is B^1 rather than B^2 . Equation 2 implies that the “incremental” benefit for agents in B from choosing B^2 rather than B^1 increases if their institutional environment in A is A^2 rather than A^1 . Note that these conditions are concerned with the property of incremental payoffs with respect to a change in a parameter value. They do not exclude the possibility that the level of payoff of one rule is strictly higher than that of the other for the agents of one or both domain(s) regardless of the choice of rule in the other domain. In such a case the preferred rule(s) will be implemented autonomously in the relevant domain, while the agents in the other domain will choose the rule that maximizes their payoffs in response to their institutional environment. Then the equilibrium of the system comprised of A and B – and thus the institutional arrangement across them – is uniquely determined by preference (technology).

However, there can also be cases in which neither rule dominates the other in either domain in the sense described above. If so, the agents in both domains need to take into account which rule is institutionalized in the other domain. Under the supermodularity condition, there can then be two pure Nash equilibria (institutional arrangements) for the system comprised of A and B , namely, $(A^1; B^1)$ and $(A^2; B^2)$. When such multiple equilibria exist, we say that A^1 and B^1 , as well as A^2 and B^2 , are “institutional complements.”

If institutional complementarity exists, each institutional arrangement characterizes as a self-sustaining equilibrium where no agent has an incentive to deviate. In terms of welfare, it may be the case that possible overall institutional arrangements are not mutually Pareto comparable or that one of them could be even Pareto sub-optimal to the other. In these cases, history is the main force determining which type of institutional arrangements is likely to emerge, with the consequence that suboptimal outcomes are possible.

Suppose, for instance, that $(A^2; B^2)$ is a Pareto-superior institutional arrangement in which $u(A^2; B^2) > u(A^1; B^1)$ and $v(B^2; A^2) > v(B^1; A^1)$. However, for some historical reason A^1 is chosen in domain A and becomes an institutional environment for domain B . Faced with this institutional environment, agents in domain B will correspondingly react by choosing B^1 . Thus the Pareto-suboptimal institutional arrangement $(A^1; B^1)$ will result. This is an instance of coordination failure in the presence of indivisibility.

Obviously, there can also be cases where $u(A^2; B^2) > u(A^1; B^1)$ but $v(B^1; A^1) > v(B^2; A^2)$. This is an instance where the two viable institutional arrangements cannot be Pareto ranked. Agents exhibit conflicting interests in the two equilibria, and the emergence of one institutional arrangement as opposed to the other may depend on the distribution of decisional power. If for some reasons agents choosing in domain A have the power to select and enforce their preferred rule, arrangement $(A^2; B^2)$ is the most likely outcome. Alternatively, agents choosing in domain B will force the society to adopt $(B^1; A^1)$.

Pagano (1992) and Pagano and Rowthorn (1994) are two of the earliest analytical contributions to institutional complementarity. In their models, the technological choices take as parameters property rights arrangements whereas the latter are made on the basis of given technologies. The complementarities of technologies and property rights create two different sets of organizational equilibria. For instance, strong rights of the capital owners and a technology with a high intensity of specific and difficult to monitor capital are likely to be institutional complements and define one possible organizational equilibrium. However,

also strong workers' rights and a technology characterized by a high intensity of highly specific labor can be institutional complements and define an alternative organizational equilibrium. The organizational equilibria approach integrates the approaches *à la* Williamson (1985), which have pointed out the influence of technology on rights and safeguards, and the views of the radical economists (see, for instance, Braverman 1974), who have stressed the opposite direction of causation. The complementarities existing in the different organizational equilibria integrate both directions of causation in a single analytical framework. A similar approach has been used to explain organizational diversity in knowledge-intensive industries, such as software (Landini 2012, 2013).

Institutional complementarities characterize also the relations between intellectual property and human capital investments. Firms owning much intellectual property enjoy a protection for their investments in human capital, which in turn favors the acquisition of additional intellectual property. By contrast other firms may find themselves in a vicious circle where the lack of intellectual property inhibits the incentive to invest in human capital and low levels of human capital investments involve that little or no intellectual property is ever acquired (Pagano and Rossi 2004).

Less formal approaches to institutional complementarities have also been adopted. In their seminal contribution, Hall and Soskice (2001) develop a broad theoretical framework to study the institutional complementarities that characterize different varieties of capitalism. Having a specific focus on the institutions of the political economy, the authors develop an actor-centered approach for understanding the institutional similarities and differences among the developed economies. The varieties of capitalism approach has inspired a large number of applications to the political economy field. To give some examples, Franzese (2001) and Höpner (2005) investigate the implications for industrial relations; Estevez-Abe et al. (2001) use the approach to analyze social protection; Fioretos (2001) considers political relationships, international

negotiations, and national interests; Hall and Gingerich (2009) study the relationship among labor relations, corporate governance, and rates of growth; Amable (2000) analyzes the implications of institutional complementarity for social systems of innovation and production.

In addition to institutional variety, the notion of institutional complementarity has also motivated studies on institutional change (Hall and Thelen 2009; Boyer 2005). In these works institutional complementarity is often presented as a conservative factor, which increases the stability of the institutional equilibrium (Pagano 2011). In the presence of institutional complementarity change requires the simultaneous variation of different institutional domains, which in turn demands high coordination among the actors involved. Sometime, institutions themselves can act as resources for new courses of action that (incrementally) favor change (Deeg and Jackson 2007).

Alongside contributions on the distinct models of capitalism, the concept institutional complementarity has found application also in other domain of analysis. Aoki (1994), for instance, studies the role of institutional complementarity in contingent governance models of teams. Siems and Deakin (2010) rely on an institutional complementarity approach to investigate differences in the business laws governing in various countries. Gagliardi (2009) argue in favor of an institutional complementarity relationship between local banking institutions and cooperative firms in Italy. Bonaccorsi and Thuma (2007), finally, use the idea of institutional complementarity to investigate inventive performance in nano science and technology.

Institutional Economics

Ringa Raudla

Faculty of Social Sciences, Ragnar Nurkse School of Innovation and Governance, Tallinn University of Technology, Tallinn, Estonia

Abstract

Institutional economics is interested in the interactions between institutions and the economy: how institutions influence the functioning, performance, and development of the economy and, in turn, how changes in the economy influence the institutions. Institutional economics studies the impact of institutions on economy, how institutions evolve, and how they could be improved. In furthering institutional economics, more extensive exchanges between the communities of institutional economics and law and economics would be fruitful. Those interested in institutional economics should certainly be more aware of developments in law and economics and utilize these insights in their further research – and vice versa.

Definition

Institutional economics is interested in the interactions between institutions and the economy: how institutions influence the functioning, performance, and development of the economy and, in turn, how changes in the economy influence the institutions. Institutional economics

studies the impact of institutions on economy, how institutions evolve, and how they could be improved.

Introduction

For readers from outside the discipline of economics, the adjective “institutional” in front of “economics” in the title of this entry may appear somewhat redundant. It would seem obvious that in order to understand what is going on in the economy, it is necessary to examine the institutions that the economy is embedded in. Thus, one could ask: why it is necessary to emphasize the term “institutions” in “institutional economics” given that “economics” should, logically, already include the analysis of “institutions”?

The reason for including the term “institutional” in front of “economics” is that neoclassical economics, which has constituted the economic mainstream since the mid-twentieth century, has paid only very limited attention to institutions. This has, at least partly, been due to the fact that economics came to be defined by its *method* (i.e., formalistic analysis of rational choice), rather than its *object* of analysis (i.e., the economy).

Fortunately, despite the lure of the mainstream economics in which the method was given prominence over the subject matter, a sufficient number of economists have been interested in real-life economies. In studying the *economy* as a subject matter, however, institutions cannot be ignored for too long before the analysis becomes stalled. Thus, in recent decades, institutions have returned to economic analysis, with an increasing number of economists paying attention to the role of institutions when explaining what is going on in the economy.

The law and economics movement has certainly played an important role in bringing “institutions” (like law) back into economics. Indeed, institutional economics and law and economics are closely related: they have similar intellectual roots, common pioneers, and overlapping research agenda. Law is, obviously, one of the most important “institutions” that are studied in institutional economics. Some would even say

that “law and economics” could be viewed as one of the subfields or “building blocks” of institutional economics.

What Is Institutional Economics?

Most broadly speaking, institutional economics is interested in the interactions between institutions and the economy: how institutions influence the functioning, performance, and development of the economy and, in turn, how changes in the economy influence institutions. Institutional economics studies the impact of institutions on the economy, how institutions evolve, and how they could be improved.

When studying the economic system, institutional economics assumes that “institutions matter” since institutions are the key element of any economy and should hence be placed at the center of analysis. Various definitions of the term “institution” have been offered by different authors. Broadly speaking, institutions can be defined as formal and informal rules, including their enforcement mechanisms. Douglass North, who can be considered as one of the “bridge-builders” between the old and new institutional economics, has defined institutions as “the rules of the game in a society” (1990, p. 3) or, more specifically, “humanly devised constraints that structure political, economic and social interaction” (1991, p. 97). According to North, institutions consist of both “informal constraints” (e.g., customs, traditions, and codes of conduct) and “formal rules” (e.g., constitutions and laws).

Some analysts (especially in the new institutionalist camp) have considered it useful to distinguish between different levels of analysis in examining institutions (see, e.g., Williamson 2000; North 1990): (1) the “highest” or so-called “social embeddedness” level entails norms, customs, and traditions; (2) the next level – the “institutional environment” – comprises of constitutions, laws, and political institutions; and (3) the lowest level of analysis looks at “institutional arrangements” or “governance arrangements” (e.g., vertical integration, franchising) and “organizations” (e.g., political parties, firms,

and trade unions). Institutional economics considers all these different levels of analysis as worthy pursuits (including interactions between the different levels), though admittedly, a lot more progress has been made on the third level of analysis than on the first two, where a lot of research still remains to be done.

Roots of Institutional Economics

The roots of institutional economics go back (at least) to the German historical school (represented, e.g., by Gustav von Schmoller, Wilhelm Roscher, Werner Sombart, and Max Weber) and the American institutionalist school (represented, e.g., by John Commons, Thorstein Veblen, and Wesley Mitchell) (for more detailed discussions, see, e.g., Medema et al. 1999; Rutherford 1994). The historical school dominated the discipline of economics in Germany from 1840s to 1940s, whereas the American institutionalist school had its peak during the interwar period. While there were important differences between these two schools and also between the individual thinkers within them, what they had in common was the focus on the role of institutions in shaping economic outcomes and their critique of the neoclassical approach to economic analysis (especially the formalistic aspects of it). The German historical school underscored the importance of sensitivity to specific cultural and historical circumstances in economic analysis (resulting in their emphasis on using empirical data to ground economic theories). The American institutionalist school emphasized the relevance of institutions (including the role of the laws and the state) in analyzing the economy. Commons (1924), for example, examined the legal underpinnings of the capitalist economic system; he demonstrated how evolutionary changes in the economic domain (e.g., with regard to what types of activities were deemed reasonable) facilitated specific changes in laws (e.g., the transformation of how the concept of property was legally defined) and how these changes, in turn, facilitated specific forms of economic activity. The American institutionalist school was also skeptical of the notion of the fixed preferences of individuals and emphasized that individual preferences can be shaped by

the institutions that surround them (e.g., via forming habits, as argued by Thorstein Veblen). In addition, the institutionalists criticized the static approach of the neoclassical economics and emphasized the evolutionary nature of economy (and hence the focus on change, technology, and innovation in economic analysis) (see, e.g., Veblen 1898).

In the postwar period, the popularity of the institutionalist approaches waned and economics became dominated by neoclassical economics. However, the institutionalist traditions were carried on by economists like Clarence Ayres, Karl Polanyi, John Kenneth Galbraith, Allan Gruchy, Simon Kuznets, Gunnar Myrdal, Ragnar Nurkse, Joseph Schumpeter, and others. In law and economics, the institutionalist traditions have been carried on by Allan Schmid, Warren Samuels, Nicolas Mercuro, and Steven Medema.

Different Approaches Within the “Modern” Institutional Economics

Until a decade or so ago, authors writing about “institutional economics” considered it necessary to distinguish between “old” and “new” institutional economics (for a more detailed discussion of the differences between these two camps, see, e.g., Rutherford 1994). “Old” institutionalism referred to researchers (e.g., Wendell Gordon, Allan Gruchy, Philip Klein, Marc Tool, Warren Samuels, Allan Schmid) following the traditions of John Commons, Thorstein Veblen, Wesley Mitchell, and others. The “new” institutional economics referred to the developments in economics that started in 1960s (led by Ronald Coase, Douglass North, and Oliver Williamson) when institutions were (at least to some extent) “brought back in” to the economic mainstream. Many authors in the emerging new institutional economics camp (e.g., Robert Sugden, Andrew Schotter, Mancur Olson, and Richard Posner) attempted to use the analytical tools of neoclassical theory to explain the emergence and impacts of institutions, with a specific attention to transaction costs, property rights, and contractual relations. In more recent years, however, the academics in the new institutionalist camp have increasingly moved away from the assumptions of neoclassical economics.

While one can still observe differences between the “old” and “new” camps, one can also talk more generally about (modern) institutional economics. In the light of the recent convergences between the camps (see, e.g., Dequech 2002), it would be helpful to offer a more *synthesized* view of what institutional economics is about. Thus, this entry tries to delineate the “common” ground of different institutional approaches by focusing on issues that many (if not most) researchers involved in doing research in institutional economics would agree are important.

Still, it is worth keeping in mind that institutional economics entails a rather diverse (and to some extent also conflicting) set of approaches. These different research streams vary with regard to the substantive questions studied and the methodology applied. Thus, institutional economics is not a single, unified, all-embracing, and well-integrated theory, proceeding from a set of common assumptions and hypotheses. Instead, it consists of different “building blocks,” coming from different traditions. Furthermore, it is worth emphasizing that institutional economics is an openly interdisciplinary endeavor, which draws on other disciplines (like sociology, psychology, anthropology, history, political science, public administration, and law) in order to understand and explain the role of institutions in economic life.

Differences Between Institutional Economics and Neoclassical Economics

Although at least some of the topics that used to be the playground of institutional economics have gradually found their way into the economic mainstream and there is a growing consensus about the importance of institutions in influencing economic growth (see, e.g., Acemoglu et al. 2005), it is still too early to say that “we are all institutionalists now.” Hence, a few remarks on how the *institutional* approach in economics differs from the *neoclassical* approach are still necessary. It is worth keeping in mind, though, that the different institutionalist camps differ somewhat with regard to their “distance” from the orthodox neoclassical economics: those who are closer to the “old” institutionalist

traditions are further removed from the neoclassical assumptions than those in the “new” institutionalist camp.

In sum, the differences between the (mainstream) neoclassical economics and institutional economics are the following (for a more systematic comparison, see, e.g., Hodgson 1988; Medema et al. 1999):

First, while neoclassical economics proceeds from the assumption of “rational” individuals who maximize their utility (*homo oeconomicus*), the institutionalist approach takes a more realistic view of individual behavior: it regards individuals as being purposeful but only *boundedly rational*. Unlike orthodox economics, institutional economics emphasizes the importance of severe information problems (including uncertainty about the future) and the costs involved in obtaining necessary information. Proponents of institutional economics have hence criticized the orthodox approaches for simply “assuming away” the information problems and “assuming” perfect knowledge.

Second, in contrast to the neoclassical approach of treating the tastes and preferences of individuals as “given” or “fixed” (at least for the purposes of analysis), most institutional economists view the individuals as “social beings” and hence consider it necessary to proceed from the assumption that preferences are *malleable* and that *changes* in preferences should be analyzed as well, including the role of institutions in molding individual preferences and purposes (via changes in habits, as argued by Hodgson 1988, 1998).

Third, while neoclassical economics is concerned with states of *equilibria* and equilibrium-oriented theorizing (focusing on “mechanistic” optimization under static constraints), most institutional economists prefer to take a more evolutionary view of economic phenomena and also institutions. They emphasize that economic development has an *evolutionary* nature and hence prefer dynamic modes of theorizing, with a focus on longer-run processes of continuity and change, entailing path dependencies, transformations, and learning over time. Institutional economics is also interested in the

evolutionary nature of the interactions between institutions and the economy. Further, while the neoclassical economics treats technology as “given” (or exogenous), institutional economics emphasizes the importance of examining the role of technological changes (and their interactions with institutions) in economic development.

Fourth, while neoclassical economics tends to treat the use of *power* as given (and accept the power structure as it is), at least some institutional economists (especially those with closer ties to the “old” institutional economics) are concerned with how power is actually deployed in the economic, political, and societal settings. Power is deemed important because power relations influence who gets to shape the institutions (including legal rules), whose values dominate, and whose “interests” are to be regarded as “rights.” The allocation of rights, in turn, would influence the distribution of power in society (see, e.g., Acemoglu et al. 2005; Furubotn and Richter 1997; Medema et al. 1999).

Why and How Do Institutions Matter?

Most generally speaking, institutions “matter” for the economy because the structures entailed in the institutions influence the behavior of the economic actors, which in turn influences the functioning and performance of the economy. The influence from the “institutions” to the “economy,” however, is not unidirectional: changes in the economy can bring about changes in institutions as well and, hence, it would be more accurate to talk about mutual interactions between institutions and the economy (see, e.g., Medema et al. 1999). In other words, we should not take a deterministic view of institutions according to which institutions always *determine* the actions of individuals: the causal arrow can go in the other direction as well. “Actors and structure, although distinct, are thus connected in a circle of mutual interaction and interdependence” (Hodgson 1998, p. 181).

How do institutions influence the behavior of economic actors? There are different ways to answer the question. The answer closest to mainstream economics is that institutions shape the

“choice set” available to the economic actors and “structure the incentives” of the actors (hence making a certain course of action more attractive than other courses) and thus steer individual behavior via affecting the costs and benefits associated with different types of actions (including engaging in different types of economic activities) (see, e.g., Acemoglu et al. 2005; Eggertsson 1990; Furubotn and Richter 1997; North 1991). Other answers point to the more “sociological” and deeper “psychological” mechanisms and emphasize role of institutions in shaping the habits and, through that, also the preferences of individuals, which, in turn, would influence their choices and actions (see, e.g., Hodgson 1988, 1998).

At the most basic level – and this is something that all institutionalists agree with – institutions influence the interactions of economic actors by providing “order” and reducing uncertainty in exchange. Given that institutions outline the “rules of the game” (which provide boundaries, constraints, and patterns for behavior), they provide economic actors with information about the potential behavior of *other* actors and hence help to establish baseline conditions for interactions between economic agents. Hence, institutions allow individuals to make reliable predictions about what *other* economic agents are likely to do in any given circumstance, which allows them to proceed with decision-making, negotiations, and exchange with at least some level of certainty (see, e.g., Hodgson 1988; Kasper and Streit 1998; Nelson and Sampat 2001; North 1991). Thus, institutions can both *constrain* and *enable* individual actions, e.g., by providing information about the behavior of others, defining pathways for doing things, allowing coordinated actions, and limiting opportunistic and arbitrary behavior.

Many institutional economists have emphasized that institutions influence the size of *transactions costs* associated with exchange relations (see, e.g., Furubotn and Richter 1997; Kasper and Streit 1998; North 1991). Transaction costs involve different cost associated with exchange processes, including search and information costs (e.g., discovering what one wants to buy, who the sellers are, and what the prices are),

bargaining and decision costs (e.g., associated with drawing up a contract), and policing and enforcement costs (see, e.g., Coase 1960; Furubotn and Richter 1997; North 1991). For example, provisions of contract law can help to lower the costs of concluding and enforcing contracts (e.g., the possibility to turn to courts in case of a breach reduces the need undertake “private” safeguarding measures by the parties themselves) and to hence facilitate impersonal contracting between strangers.

It has to be emphasized, however, that the institutions that have evolved in any given country do not necessarily *guarantee* a well-functioning economy and fast economic development. The institutions that have emerged can also be highly inefficient and entail elements that clearly hinder technological advances and economic development and growth (Freeman and Perez 1988; North 1990, 1991; Nelson and Sampat 2001).

Some Examples of How Institutions Influence Economic Performance

While lot of research still needs to be undertaken in order to achieve fuller understanding of the role of institutions in economic development, a number of insightful studies have been conducted so far. A complete overview of these achievements is certainly beyond the scope of this entry. Thus, the examples below constitute only a small portion of the body of research in institutional economics and should be viewed as indicative rather than exhaustive.

Markets as Institutions

Mainstream economics tends to treat the market as some sort of a “natural” feature of a social domain, an aggregate of individual bargains, resulting from free exchange between economic agents – almost as “an ether in which individual and subjective preferences relate to each other, leading to the physical exchange of goods and services,” independent of institutions (Hodgson 1988, p. 178). In contrast, for most institutional economists, the market should be conceived of as

an institution (or a set of institutions), involving “social norms, customs, instituted exchange relations and – sometimes consciously organized – information networks” (Hodgson 1998, p. 181). Institutional economics emphasizes that market institutions (and the institutions the market is embedded in) can play an important role in lowering transaction costs and hence facilitate more exchange relations.

Institutionalist research has also examined the role of the state in creating (what mainstream economists call) “free markets.” Karl Polanyi (1944), for example, shows, in his study of the Industrial Revolution in Great Britain, that the development of free markets in the eighteenth and nineteenth centuries actually involved a significant increase in the activities of the government: more legislation was called for and more administrators needed to monitor and safeguard the free working of the market system. In other words, the creation of “free markets” implied an increase in the control, regulations, and intervention by the state. The same applies today: “every successful market economy is overseen by a panoply of regulatory institutions, regulating conduct in goods, services, labor, assets, and financial markets” (Rodrik 2000, p. 7). The “freer” the markets, the greater the vigilance that may be required from the regulatory institutions (e.g., in the field of antitrust, financial regulation, securities legislation, etc.) (ibid).

In the light of these findings, some institutionalists emphasize that the dichotomy between regulation vs deregulation (or intervention vs nonintervention or “more” vs “less government”) is false. Instead, one should ask which *type* of regulation and intervention the state is engaged in (and for what ends) and whose “interests” are protected as “rights” by the state (Hodgson 1988; Medema et al. 1999). For example, if the government relaxes regulations pertaining to workplace safety, it expands the set of rights of employers and narrows the set of rights of employees – and vice versa when these regulations are toughened. In either case, the government is “present” – via the legal framework and the mechanisms of enforcement (Medema et al. 1999).

Property Rights

An important set of institutions that has captured the attention of many institutional economists – both in the “old” and “new” camps, from Commons (1924) to North (1990) – involves *property rights*. Again, while neoclassical economics takes property rights as “given” (i.e., perfectly defined), institutional economists take a much closer look at the actual definition, delineation, allocation, and enforcement of property rights and how these influence exchange relations and other economic activities. Institutionalists from different traditions agree that the specific content of property rights (e.g., control rights over assets or resources) and the way they are enforced influence the allocation and use of resources. As Rodrik (2000, p. 6) puts it, “an entrepreneur would not have an incentive to accumulate and innovate unless s/he has adequate control over the return of the assets that are thereby produced or improved.” Thus, for example, when property rights are not credibly secured (e.g., when there is a threat of expropriation by the government or unilateral seizure by another private actor), entrepreneurs are less likely to adjust (efficiently) to changes in technology, to invest (e.g., in research and development, which facilitates technological change), and to innovate. In contrast, secure property rights encourage firms to make higher value-added investments with longer-term time horizons (Keefer and Knack 1997).

Institutional economists have also examined the role of the *state* in protecting property rights. On the one hand, it is emphasized that protection of individual property entails legal structures for recognizing, adjudicating, and enforcing these rights, which can be provided by the state (e.g., Sened 1997). On the other hand, it is argued (especially by the new institutionalists) that the state can also pose a danger to private property through expropriation (Furubotn and Richter 1997). Bringing these two arguments together, Douglass North (e.g., 1990, 1991) has argued that economic development is fostered by an institutional environment in which the state is sufficiently strong to protect the private parties from seizing each others’ property but can at the same time make a credible commitment not to

expropriate the very same property it is defending and securing. As Hodgson (2004) puts it, “For private property to be relatively secure, a particular form of state had to emerge, countered by powerful and multiple interest groups in civil society. This meant a pluralistic state with some separation of powers, backed up by a plurality of group interests in the community at large.” In his empirical studies, Douglass North has argued that the establishment of clear and secure property rights played a major role in the economic development and rise of the “West.” Establishing secure property rights (with a credible commitment by the state to respect and secure them) allowed, for example, the emergence of capital markets and the employment of technology necessary for industrial production (see, e.g., North 1990, 1991). Many other studies (e.g., Acemoglu et al. 2005; Keefer and Knack 1997) have confirmed that finding.

Another discussion concerning property rights pertains to the question of whether the policy instrument of more extensive allocation of property rights implies “more” state or “less” state. Some economists in the new institutionalist camp (e.g., Demsetz, Alchian) regard clearer definition and allocation of property rights (especially the extension of private property) as “solutions” to different types of market failures, hence allowing the “lessening” of the need for government intervention. Hodgson (1988, p. 152), in contrast, has pointed out that by expanding the domain of formal property rights, the state still remains engaged, but in a different way – through the extension of litigational activity. Chang (2007), among others, has also warned us of the dangers of using the institutional prescription of “private property rights” as the main “solution” for guaranteeing economic development (see also Rodrik 2000). Indeed, a whole stream of research examines the conditions under which different types of ownership – private property, common property, state property, and various hybrid forms (like the township and village enterprises in China) – lead to optimal use of resources. Elinor Ostrom (e.g., 1990), for example, has shown that in the case of common-pool resources, common property can (when

combined with suitable institutional arrangements) lead to a better use of natural resources (e.g., fish stock, forests, water) than either privatization or nationalization.

Political Institutions and Bureaucracy

One of the building blocks in the institutionalist literature looks at the impacts of specific features of *political institutions* (including constitutions) on economic performance. The starting point for many of these studies is that the balance and separation of powers and the number and power of veto players are likely to influence the general character of policy action (including the levels of decisiveness and credibility) and also specific features of policies and laws the governments adopt, which, in turn, can influence economic performance. For example, it has been examined how the level of democracy (and the level of inclusiveness in governance) but also specific constitutional features – like government type (presidential vs parliamentary), electoral rules (e.g., plurality vs proportional), the organization of the judiciary, and vertical separation of powers – influence economic performance (see, e.g., Acemoglu et al. 2005; Persson and Tabellini 2003; Rodrik 2000).

Yet another stream examines the role of administrative structure, public administration, and the characteristics of bureaucracy in the economic growth and development. Evans and Rauch (1999) show that economic growth is higher in those developing countries where the bureaucracies entail more Weberian elements (e.g., recruitment based on merit and predictable long-term career paths). They argue (drawing, e.g., on Weber [1904–1911] 1968 and also Polanyi 1944) that merit-based recruitment and long-term careers facilitate higher competence of public administrators, lower levels of corruption, and long-term orientation. These factors, in turn, facilitate the design and implementation of policies that can help to promote growth, e.g., the provision of long-term (public) investments that complement those made in the private sector and helping private sector actors to overcome coordination and information problems (see also Rodrik 2000; Wade 1990).

Concluding Remarks

Despite an increasing number of studies examining the links between institutional setting and economic performance, we are only at the beginning of the journey to understand the interrelations involved and which institutions constitute a “good fit” in different countries and contexts. As Chang (2007, p. 3) puts it: “We are still some way away from knowing exactly which institutions in exactly which norms are necessary, or least useful, for economic development in which contexts.”

As the experience of transition, emerging, and developing economies has demonstrated, in further studies it would be necessary to explore the effects of different *configurations* of (complementary) institutions rather than examining the effects of specific institutions (e.g., the establishment of private property rights or the adoption of a new contract law) in isolation.

Also, the relationships between informal and formal institutions still need to be examined further. It is clear that the effectiveness of “formal” institutions (e.g., laws and regulations) depends on whether they fit sufficiently well with the “informal” institutions (like norms and customs), which in turn influences, for example, how well institutional transplants (from one country to another or implementing the “best practice” blueprints) can work. However, we are still far from completely understanding how informal forms emerge and persist, how such informal norms interact with formal norms, and how that, in turn, influences specific economic activities in a given country.

Finally, we still have only limited knowledge of how institutions conducive to economic development in specific contexts can be “built.” These are all important arguments for undertaking more in-depth qualitative and comparative studies in the field.

In furthering institutional economics, more extensive exchanges between the communities of institutional economics and law and economics would be fruitful. Those interested in institutional economics should certainly be more aware of developments in law and economics and utilize these insights in their further research – and vice versa.

Institutional Review Board

Roberto Ippoliti

Department of Management, University of Turin, Turin, Italy

Scientific Promotion, Hospital of Alessandria – “SS. Antonio e Biagio e Cesare Arrigo”, Alessandria, Italy

Abstract

Institutional Review Board (IRB) are independent institutions aimed at approving, monitoring and reviewing human experimentations in order to protect research subjects’ rights from the necessity to increase the current medical knowledge.

After a brief historical introduction of humans experimentation, this section presents American and European regulation of this specific institution, as well the main related issues in Law and Economics.

Synonyms

Ethical review board; Independent ethics committee

Definition

Institutional Review Board (IRB) is a committee designated to approve, monitor, and review human experimentations in order to protect research subjects' rights.

IRB and its Evolution

Institutional Review Board (IRB), also known as independent ethics committee or ethical review board, is a committee designated to approve, monitor, and review human experimentations in order to protect research subjects' rights.

The matter of research subjects' rights was first addressed after the end of World War II, when Nazi experiments on prisoners and Jews were discovered. Those researches were motivated by racial and political conflict and the idea of rights for those kept in Nazi concentration camps held no meaning. The subjects were coerced into participating and there was no informed consent about potential related expected and unexpected adverse events (e.g., their death). The Nazi experiments were aimed at supporting the Nazi racial ideology, as well as at improving the survival and rescue of German troops, by testing medical procedures and pharmaceuticals.

After that experience, society felt that it was its duty to prevent research involving people who were used as test subjects not of their own free will and to check the scientific aims of research studies. Thus, The Nuremberg Code of Ethical Human Subjects Research Conduct (1947) was drafted. This was the first international document on human experimentation and research subjects which highlighted the main right of patients: voluntary consent of human subjects involved in clinical trials. Obviously, this information concerns risk-benefit outcomes of experiments, i.e., both expected effectiveness and potential related expected/unexpected adverse events. However, other examples of inhuman clinical research were necessary to develop a systematic review of these studies by independent institutions, for

example, the *Tuskegee syphilis experiment*, which was a clinical study conducted by the US Public Health Service to study the natural progression of untreated syphilis, or the *Vipeholm experiments*, which was sponsored by the sugar industry and dentist community, in order to determine whether carbohydrates affected the formation of cavities. In the former study, research subjects were rural American men who thought they were receiving free health care from the US government, even if they were never told they had syphilis nor were they ever treated for it (see Thomas and Quinn (1991)). In the latter case, patients of a Swedish mental hospital were fed large amounts of sweets to provoke dental caries, violating the basics of medical ethics (see Gustafsson et al. 1954).

Over the years, that Code has been followed by other international documents, among which one of the most important was the Declaration of Helsinki on Ethical Principles for Medical Research Involving Human Subjects (1964). This international document was developed by the World Medical Association in 1964 as a means of governing international clinical research. It is mainly a set of guidelines for medical doctors conducting biomedical research involving human subjects, and it includes the principle that research protocols should be reviewed ex ante by an independent committee. According to its recommendations, a technical board must review each clinical trial before enrollment can start. In other words, a third party has the duty to guarantee the main principles established by the aforementioned international code: patient information and scientific validity of protocols. Another international guideline is proposed by the International Conference on Harmonisation of Technical Requirements for Registration of Pharmaceuticals for Human Use (ICH), which is a project that brings together the regulatory authorities of Europe, Japan, and the USA, as well as experts from the pharmaceutical industry, to discuss scientific and technical aspects of pharmaceutical product registration. ICH provides good clinical practice (GCP), i.e., an international quality standard that governments can transpose

into regulations for clinical trials involving human subjects (ICH Topic E 6 (2002)). According to ICH-GCP, an IRB should safeguard the rights, safety, and well-being of research subjects, with a particular attention to trials that may include vulnerable subjects (e.g., pregnant women, children, prisoners). A European standard for clinical trials and patient protection is the ISO 14155, which is valid in the European Union as a harmonized standard good clinical practice (i.e., ISO-GCP).

According to international documents and guidelines, both in Europe and in the USA, a protection system has been developed through the years, based on this Institutional Review Board (IRB). In the United States (USA), Title 45 of the Code of Federal Regulations, part 46 (revised 2009) – which is the reference regulation for US IRB – identifies this board as an appropriately constituted group that has been formally designated to review and monitor biomedical research involving human subjects, with the authority to approve or disapprove research. The purpose of IRB review is to assure that appropriate steps are taken to protect the rights and welfare of humans involved as subjects in the clinical trials, reviewing the research protocol and related materials (e.g., informed consent documents and investigator brochures). According to Directive 2001/20/EC (2001), the European Union (EU) recognizes this board as an independent body in a member state, consisting of health-care professionals and nonmedical members, whose responsibility is to protect the rights, safety, and well-being of human subjects involved in a trial and to provide public assurance of that protection, by, among other things, expressing an opinion on the trial protocol, on the suitability of the investigators and the adequacy of facilities, and on the methods and documents to be used to inform trial subjects and obtain their informed consent.

Considering their composition, FDA's requirements is set in Title 21 of the Code of Federal Regulations, part 56 (revised 2013) – which is an additional regulation for US IRB that oversee clinical trials involved in new drug applications – suggesting that an IRB must have at least five

members with enough experience, expertise, and diversity to make an informed decision on whether the research is ethical, informed consent is sufficient, and appropriate safeguards have been put in place. Moreover, the regulation states that if a study that includes vulnerable populations is under investigation, the IRB should have members who are familiar with these groups (e.g., an IRB has to include an advocate for prisoners when considering research that involves them). The European Directive 2001/20/EC (2001) does not specify the composition of each IRB, which is regulated at the national level by each member state.

Several law and economics issues are related to IRBs and their activity. Just to cite a few, Calabresi (1969) focused on the generational conflict, suggesting that IRB should be an expression of the value of research that involves human subjects and how it is necessary to achieve an adequate balancing of present against future lives. Other researchers focus on the effectiveness of the IRB decision-making process, highlighting how these boards have exercised primary oversight responsibility for human research subject, continuing to be often incapable of reviewing complex research protocols effectively (Hoffman 2001; Coleman 2004). Finally, proposing the ideal “Market of Human Experimentation,” Ippoliti (2013a, b) analyzes the relation between IRB activity and the transaction costs to achieve an exchange of information for innovation, suggesting the main impact on countries' competitiveness.

Another interesting topic related to the IRB members, which should be deeply analyzed from a law and economic prospective, concerns the undue influence of pharmaceutical companies and the related economic interests involved in the ethical decisions. Just to give an idea of the issue, Campbell et al. (2006) analyze the relation between IRB members and industry, suggesting that 36 % of these members had had at least one relationship with for-profit institutions in the past year. Moreover, authors denote that of the respondents, 85.5 % said they never thought that the relationships that another IRB member had with the industry affected his or her

IRB-related decisions in an inappropriate way. The economic undue influence is even more important considering the US market, where some IRB reviews are conducted by *for-profit* organizations – i.e., commercial IRBs (Emanuel et al. 2006).

Insurance Market Failures

Donatella Porrini

Department of Management, Economics, Mathematics and Statistics, University of Salento, Lecce, Italy

Abstract

Insurance market is characterized by failures that impose particular negative consequences; given the failures, different remedies may improve the market outcome. On one hand, the insurance market is characterized by asymmetric information, i.e. moral hazard and adverse selection, and to correct the consequent severe market failures, monitoring and risk classification can be implemented. On the other hand, the insolvency issue: given the enormous amounts of funds in the hands of insurance companies, their default would have an extreme impact, and regulation is necessary to guarantee the payback for policyholders and beneficiaries.

Definition

Insurance is an instrument to give protection against the risk resulting from various perils or hazards, such as health risks, invalidity or death, accidents, unemployment, theft, fire, and many more. Contracts are offered by insurance companies providing risk-sharing mechanisms that allow their customers to replace these risks. Insurance market is characterized by failures that impose particular negative consequences on one or both market sides: given the failures, different remedies may improve the market outcome.

Introduction

Insurance plays three economic functions: (i) the transfer of risk from a risk-averse individual to the risk-neutral insurer, (ii) the pooling of risk so that the “uncertainty” of each insured becomes the

“certainty” of the insurance companies that this risk will occur to a percentage of their customers, and (iii) the allocation of risk for which each insured pays a price that should reflect the risk he contributes (Abraham 1995).

For these three reasons, insurance contracts increase social welfare while at the same time induce people to have a preventive behavior and contribute to internalize damage. At a macro-economic level, decreasing the economic effects of risks, insurance encourages companies to operate in risky sector and to make investments that they would not make otherwise. Meanwhile, life insurance plays a role as a long-term investment and savings instrument (Shavell 2000).

Asymmetric Information

The insurance market is characterized by the fundamental problem of bilateral asymmetric information. On one hand, individuals do not have complete information in understanding complicated insurance contracts and lack the ability to assess the adequacy of premium to risk. On the other hand, insurers suffer from lack of information regarding the risk characteristics of individuals. This second asymmetry generates the two phenomena of moral hazard and adverse selection.

Moral hazard (hidden action) depends on the insurers’ impossibility to perfectly know the extent their customers’ behavior may affect the occurrence and/or the dimension of the loss.

To be precise, the term moral hazard refers to at least two different situations in which the insured’s behavior can affect the probability of the various outcomes: (i) situations when insurance may induce greater use of a service by an insured individual or cause the insured to exercise less care and (ii) situations when an insured individual purposely causes harm or otherwise falsifies loss in order to collect insurance benefits or to inflate the loss.

In the case of moral hazard, the insured’s behavior changes, and the insurer is unable to either predict this change in advance or to prevent

it by exempting such behavior from the insurance contract coverage (Shavell 1979).

In fact, after signing an insurance contract, the insured may have less incentive to act carefully or take preventive measures, influencing both the damage probability and/or the loss dimension.

Moral hazard, even if severe, does not cause a complete breakdown of markets, but it raises the cost of insurance and, consequently, reduces the degree of insurance coverage negatively affecting market outcomes (Tennyson and Warfel 2009).

In this case, a remedy is monitoring the insured’s behavior: *ex ante* the loss occurrence, to monitor the level of care in preventing the loss, insofar as the insured’s behavior has any influence over the risk; *ex post*, to monitor the amount of claim when loss occurs, beyond the services the claimant would purchase if not insured and assuming the insured individual can influence the magnitude of the claim. Also incentive schemes linking the price of insurance to observed past behavior (e.g., bonus/malus systems) can be used as devices to contain this problem (Derrig 2002).

Adverse selection (hidden information) refers to the inability of insurers to observe risk characteristics of their customers, leading to offer a contract based on the average risk of the entire group of customers. In this case, more high-risk individuals purchase insurance; higher payouts by insurance companies force them to raise rates which, in turn, makes the insurance less attractive to low-risk individuals.

As a consequence, this may reduce the stability of the market equilibrium, and the market may completely break down, such as the famous “market for lemons” (Akerlof 1970).

In the case of adverse selection, a remedy would be to use statistical data to separate different categories of risky individuals by classification instrument.

Theoretically in determining the premium to be charged, insurers should estimate the expected losses for each individual being insured. But given the informational asymmetry, the insurance companies apply risk classification trying to group the individuals in such a way that those with a similar loss probability are charged the

same rate. The risk classification systems are clearly supported by statistical data showing differences in the event rate in different groups (Porrini 2015).

In practice, insurers have to identify risks that are independent, uncorrelated, and equally valued and to aggregate them in order to reduce the total risk of the set. An efficient risk classification reduces adverse selection, because it makes insurance more attractive to the low-risk individuals.

Classifying insurance risks increases the efficiency of contracting in terms of asymmetric information. However, the benefits are conditional on general principles, such as the non-discrimination, and generally to consumer protection issue.

Insolvency

Generally, the default of a company generates economic damages, first to shareholders, but in many cases also to the customers. Particularly, in insurance market, the insured individuals may lose future benefits and insurance coverage with possibly precarious economic situation in many cases and imposing to rely on a public coverage of these losses.

Moreover, this is reinforced by the consequences of the so-called inversion of the production cycle that comes from the fact that insurance services are only delivered after they are purchased and in many cases years later. This creates the necessity to monitor the financial condition and solvency of insurance companies over an extended period of time.

This feature leads potentially to insufficient capitalization and suboptimal solvency levels, by giving insurers scope for hiding poor underwriting and under-reserving, and these are motivations for government interventions aimed at monitoring to improve management discipline.

Regulation for solvency dates to the nineteenth century, when insurance insolvencies in the USA and Europe led to the establishment of state regulatory authorities. Given the social role and the involvement of insurance in the systemic risk issue (Faure and Hartlief 2003), solvency

becomes the primary focus of insurance regulation worldwide. Regulatory tools include risk-based capital requirements, electronic auditing of accounts, and a wide variety of limits on the ways that companies can invest the funds held in reserve to pay claims.

Moreover, regulation can be used to steer capital into preferred fields, given that insurance is an institution for storing and accumulating capital, competing with banking and securities firms. Although banking, insurance, and securities have traditionally been subject to different regulatory regimes, there is recently a “convergence” in the financial services marketplace that places great strain on the existing regulatory institutions (i.e., the diffusion of the business model of bank insurance).

The most common instrument of regulation for solvency consists of technical provisions that correspond to the amount required by the insurer to fulfil its insurance obligations and settle all commitments to policyholders arising over the lifetime of the portfolio. Technical provisions can be divided into those that cover claims from insurance events which have already taken place at the date of reporting and those that should cover losses from insurance events which will take place in the future.

Most countries supplement the above requirements by regulating the portfolio choices of insurance firms with the aim to ensure that insurers invest and hold adequate and appropriate assets to cover capital requirements and technical provisions.

The main focus of numerous national regulation is to ensure that insurance companies are able to honor their payment obligations in a continuous way, the most important instrument being that of a generalized capital and reserve rules, possibly supplemented by additional supervisory rules, such as investment restrictions and provisions of regular inspection by supervisory authorities.

Conclusion

Because the insurance business has become highly important to society's development, it is

relevant to find remedies to the failures that can impede a correct functioning of the market.

On one hand, the insurance market is characterized by fundamental problems of asymmetric information. Moral hazard and adverse selection play a central role in the insurance market, and to correct the consequent severe market failures, monitoring and risk classification can be implemented.

On the other hand, the insolvency issue is justified by the enormous amounts of funds and investments in the hands of insurance companies; as such, their default would have an extreme impact, and regulation is necessary to guarantee the payback for policyholders and beneficiaries.

Intellectual Property: Economic Justification

Dennis W. K. Khong
Centre for Law and Technology, Faculty of Law,
Multimedia University, Melaka, Malaysia

Definition

Economic justification for intellectual property means the economic reason for establishing and

supporting a system of intellectual property laws. It begins with the characteristics of information as public goods (Arrow 1962): non-rivalry in consumption and non-excludability. Intellectual property rights confer upon the right holders an exclusive right to legally compel users to buy a genuine product from the right holders or to obtain a license from them. Intellectual property rights are to prevent a market failure due to free-riding activities of non-payers. In general, intellectual property rights can be grouped into two families according to the function of the information therein: information as a good and information as a signal. Examples of intellectual property rights in the form of information as a good are copyright, patents, industrial designs, layout-designs of integrated circuits, and confidential information, while examples of intellectual proprietary rights in the form of information as a signal are trademarks, the tort of passing off and unfair competition, and geographical indications.

Introduction

This essay examines the economic justification for intellectual property. The economic justification begins with the twin characteristics of information as public goods: non-rivalry in consumption and non-excludability. Market failure of free riding results from the non-excludability of public goods. Granting intellectual property rights is a solution to solving this public goods problem by conferring upon the creators of new information an exclusive right. In general, intellectual property rights can be grouped into two families according to the function of the information therein: information as a good and information as a signal. Macroeconomic justifications are also discussed. Exceptions and limitations to intellectual property rights are seen as solutions to curb the ill effect of a monopoly right granted by intellectual property. Finally we examine the use of the economic justification as a yardstick to assess proposals for new forms of intellectual property rights.

Intellectual property rights are intangible rights in information. The World Trade Organization's

Agreement on Trade-Related Aspects of Intellectual Property Rights (TRIPS) requires member states to have laws protecting the seven most common types of intellectual property rights, namely, copyright, trademarks, geographical indications, industrial designs, patents, layout-designs (topologies) of integrated circuits, and undisclosed (or confidential) information. In some countries such as in the European Union, database rights are also available.

Since intellectual property rights essentially create a limited form of monopoly, it is necessary to examine the economic justification for them.

Information as a Public Good

The economic justification for intellectual property rights begins with the characteristics of information. Information is said to possess the twin characteristics of public goods (Arrow 1962): non-rivalry in consumption and non-excludability (Sidgwick 1887; Pigou 1923; Samuelson 1954).

Non-rivalry in consumption refers to the characteristic of goods being not exhaustible by consumption. In other words, a public good does not decrease in both quantity and quality as more users consume the good or when the amount of consumption of that good increases. Typically, the cost structure of a public good is said to have a fixed cost, of which is usually considered high, and zero marginal cost, that is, the cost of additional usage is theoretically zero. This quality of non-rivalry in consumption is a good characteristic because it makes the good inexhaustible for consumption and is thus an infinite good.

The second characteristic of public goods is non-excludability. Non-excludability means that once the public goods have been released or made available to the public, it is extremely difficult, if not impossible, to exclude non-payers from consuming or enjoying the benefits, or to compel users to voluntarily pay for the public goods, because it can be enjoyed without payment. It is this characteristic which is the root cause of the public goods problem. Pigou (1923) explains non-excludability

as “instances in which marginal private net product [falling] short of marginal social net product, because incidental services are performed to third parties from whom it is technically difficult to exact payment.” Non-excludability is a bad characteristic because it often leads to the problem of free riding, i.e., consumers enjoying its benefits without paying for its costs.

Using the above two characteristics as the defining criteria for public goods, it can be shown that information can be classified as public goods. By information, we do not confine it to bits of information but also include knowledge and electronic data. At the same time, we exclude from the definition of information its medium of carrier or the physical manifestation of information. For example, a novel consists of the physical medium, namely, paper and ink, and the information. Paper and ink have a cost component and by definition are rivalrous in consumption. On the other hand, the informational content of a novel, the storyline, and the plot and character development are intangible in nature and are non-rivalrous in consumption. One person’s knowledge and appreciation of the novel’s content do not hinder another person’s knowledge and appreciation of the same.

Likewise a motor vehicle such as a car contains both the physical embodiment of information and its informational content. The metal, rubber, and other materials used in manufacturing a car are merely the physical embodiment of the informational content of the design and technology behind the car. Although in this case not many people would be able to fully comprehend the technical details in the design of a car, the same analysis holds in that this information does not decrease in both quantity and quality in the hands of a person who could fully comprehend it. Moreover it is non-excludable because short of never selling to the public the said car, once the car is available in the market, a technically competent competitor might be able to reverse-engineer the design of the car without paying the original inventor, unless the force of law compels him to do so.

In the case of digital music, the music files have no physical embodiment short of some electromagnetic configurations. Digital files can be

easily copied at negligible or no reproduction cost. And once the music is made available on a digital network such as the Internet, it is extremely difficult or impossible to limit access to it to payers only. Thus digital music also exhibits the characteristics of public goods.

Market Failures

Information as public goods suffers from market failure due to free riding. Free riding or freeloading is defined as enjoying a benefit without paying for its cost. Two types of market failures may occur as a result. First is sub-optimal level of investment in the creation of information because of not taking into account the social benefits of information. The second is no or little investment in the creation of new information due to the threat of free riding.

To illustrate the first, we can use the example of computer software. A lone programmer who has no means of preventing free riding if he releases a computer program he has written will typically not be able to create a software package as comprehensive and well-designed as a piece of commercial software done by a software firm, because to develop commercial software would require a more extensive manpower and financial investment than could be shouldered by a typical lone programmer. So in the absence of the ability to obtain property rights in his software to the exclusion of non-paying customers, the lone programmer would probably develop his software in a sufficiently simple way to satisfy his own personal requirement. In other words, investment of effort by the programmer would be to the extent of marginal cost equals to marginal private benefit. This can be considered as a sub-optimal level of investment as optimality would require the programmer to take into account the social benefit of his creation and thus expand the programming effort to the extent of marginal cost equals to marginal social benefit.

The second form of market failure exists in the form of sub-optimal level of new information being created. This market failure occurs when potential copiers and users wait out for someone

else to create the new information. Since everyone is waiting for someone else to take the first step in creating new information, no one or few will end up doing the work of creation. This is akin to the case of prisoner's dilemma (Gordon 1992) where a cooperative strategy would be the optimal outcome, but since everyone's dominant strategy is to wait to free ride, the resulting Nash equilibrium is that all players will choose the free-riding strategy and no new information is created.

Solutions to Public Goods Problem

The traditional solution to the public goods problem is state provision from taxation as a means of funding. Both state provision and taxation make sense in relation to public goods, the benefits of which are enjoyed by the population at large, e.g., national defense, public health, and machineries of the government. However, it is not given that public goods must be provided by the state alone nor to be funded solely through a system of taxation. Non-state entities can be paid to provide public goods, or funding can be made through some form of nonvoluntary payment imposed on users. For example, Coase (1974) reminded us that in the 19th century, some lighthouses in England were operated by private parties. Passing ships were required to pay compulsory light dues.

In the same way, instead of relying on the state to create or fund the creation of new information, intellectual property rights as a form of property rights which allow creators to collect a user license fee become the preferred way to solve the problem of information as public goods. Indeed, Pigou (1923) in his *magnum opus*, *The Economics of Welfare*, discussed the public goods problem of scientific knowledge and the role of patent law to mitigate the problem of public goods.

There are several advantages to using intellectual property rights as a solution. First is that there will be less cross-subsiding by nonusers for the benefits of users. Using a system of intellectual property rights would mean that only users of those intellectual properties will have to pay license fees or purchase original copies.

Another advantage is that different creators will find their own profit-maximizing strategy based on what they perceive as the market demand, their own abilities, and preferences. So there is no difficulty of requiring central planning and the need for the state to decide on what information to create for its people. It also allows minority creators outside the mainstream society to cater to the demands of the members of the society at the fringe. In other words, intellectual property rights, to a certain extent, promote liberty and freedom of speech and expression.

On the other hand, intellectual property rights do not preclude state funding in the creation of new information. Indeed it is essential for the state to fund research both for its own use, such as for education and policy, and for public consumption, such as in the case of scientific research.

Intellectual property rights as a form of intangible property rights have another advantage in that it is transferable. This means that the potential value in an intellectual property can be realized by the owner selling or exclusively licensing it to another. Creators may choose this route in order to focus on the act of creation and leave the business of commodification to others.

Two Families of Intellectual Property Rights

Traditional legal treatment of intellectual property law tends to lump all different types of intellectual property rights into a single conceptual basket called “intellectual property.” Rather, all these different types of intellectual property rights are treated as discrete forms with no apparent similarities among them. Although this approach has its advantage for its simplicity, it nevertheless obscures the true nature and functions of different types of intellectual property rights. In general, intellectual property rights can be grouped into two families according to the function of the information therein. The first is information as a good, and the second is information as a signal.

Examples of intellectual property rights in the form of information as a good are copyright, patents,

industrial designs, layout-designs of integrated circuits, and confidential information. The commonality among these types of intellectual property rights is that the information so protected is an object that can be consumed to increase one’s utility, such as a story, a picture, a piece of music or art, an invention, a design, or some proprietary knowledge.

Information as a signal on the other hand covers intellectual property rights such as trademarks, passing off, and geographical indications. The information therein is not an object of consumption per se and cannot be enjoyed directly. Instead it helps us to use the market better by providing indications as to the sources and quality of goods and services associated with those intellectual property rights. Typically, information as a signal comes in the form of a brand, a logo, or an image of a personality, which may convey the origin or endorsement of a product.

These two families of information suffer from different forms of free riding and thus merit separate investigation.

Free Riding in Information as a Good

Free riding in information as a good happens when a free-rider, without the right holder’s consent, uses or reproduces an intellectual property. Thus, intellectual property rights are used to correct this market failure by granting to its creators and owners an exclusive or monopoly right to exploit the information so created (Plant 1934). Typically this occurs in two ways.

The first way of exploitation is in the form of products embodying the intellectual property, such as books, digital content, and technological inventions. As intellectual property rights give an exclusive right to the owner, the owner can then sell his products at a profit-maximizing monopoly price which is higher than their marginal costs of production. It is this higher than market competitive price which hopefully will bring excess profit sufficient to cover the high cost of the creation of the proprietary information.

The second way of exploitation is by way of licensing so that profit is made by allowing others to exploit the protected intellectual property

instead of selling products by the intellectual property owners themselves.

Free Riding in Information as a Signal

Intellectual property rights are also used to correct the market failure from free riding of information as a signal. Examples of this type of intellectual proprietary rights are trademarks, the tort of passing off in common law jurisdictions (or unfair competition in others), and geographical indications (Ritzert 2009).

Traditionally trademarks and the tort of passing off are said to protect the trade origin of or goodwill associated with the products. What this means is that the protected trademark serves as a link between the product and its originator, i.e., the trademark owner.

Businesses apply trademarks to products and services in order to distinguish the products and services originating from them from those of competitors. In a competitive market, or even in a duopoly, businesses increase profit by selling more. One of the ways of doing so is to attract and retain customers by offering a superior product compare to the competitors'. Even for market segment with low-quality products, businesses retain customers by offering products of a consistent quality. Alternatively, businesses attract customers by way of advertising in order to get potential customers familiar with their products through an advertising campaign.

Both strategies of superior or consistent product quality and advertising are not costless. A free-riding competitor may steal a trademark owner's market share by selling counterfeit products bearing the right holder's trademark without incurring the above costs. In fact, counterfeiters can do better in the short run by selling cheap, low-quality counterfeit products if quality is costly.

Trademark rights therefore grant the trademark owners an exclusive right to use his trademark for the classes of products or services it is registered to. With this exclusive right, the trademark owner can legally prevent counterfeiters from using his trademark by way of criminal and civil enforcements.

Another economic justification for trademark protection is to prevent consumer confusion. Supposing that a consumer values a genuine product highly and pays a high price for this product, but the product sold is a low-quality counterfeit, it would mean that the consumer has suffered a disutility. Trademark protection thus can be justified to prevent this form of economic transactions.

Therefore the economic functions of trademarks as intellectual property rights are to encourage optimal investment in advertising, optimal investment in product quality on the part of producers, and optimal consumption on the part of consumers (Landes and Posner 1987; Economides 1988). Without trademark rights, counterfeiters will reduce a trademark owner's incentive to promote his products bearing his trademark because part of the potential sale will be diverted to the counterfeiters as consumers are misled into buying counterfeit goods.

In addition, low-quality counterfeit goods in the market will jeopardize the trademark owner's effort in ensuring high and consistent quality of products bearing his trademark. Like in the market for lemons (Akerlof 1970), low-quality counterfeit goods will crowd out high-quality goods by the trademark owner as consumers could not differentiate the quality of counterfeit goods from genuine goods by way of observation. Under the condition of uncertainty in the quality, consumers will treat the market of the trademark goods as having an average quality and will have a lower willingness to pay, leading to a low equilibrium price. In the end, without trademark protection, low-quality counterfeit goods will crowd out high-quality genuine goods, making high-quality goods unavailable in the market.

Macroeconomic Justifications

Intellectual property rights are also justified from a macroeconomic perspective, especially in relation to intellectual property rights being incorporated into international trade treaties.

One argument, in the context of technology transfer, is that foreign businesses are reluctant to introduce or bring in new technology or

know-how to a country which does not have sufficiently broad and strong intellectual property rights protection. Intellectual property protection is seen as a pull factor for foreign investment, be it technological transfer or sending the design of a product to be manufactured in the receiving country (Mansfield 1995; Fink and Maskus 2005). Hence, intellectual property is argued as an exogenous growth factor.

Another macroeconomic justification builds on the relationship between intellectual property rights and economic growth (Gould and Gruben 1996). For example, businesses may earn higher profits with trademark protection. In addition, businesses are seen as having strong incentive to develop new knowledge and technology with copyright and patent protections (Sweet and Maggio 2015). Nevertheless, evidence of positive correlation between intellectual property rights and economic growth is ambiguous in many sectors (Aziz 2003; Yueh 2007).

Economic Justifications Versus Motivation

Economic justifications for intellectual property right are theoretical reasons or, at most, plausible empirical support for a system of intellectual property law. Empirical studies have uncovered other reasons and personal motivations for creators to create new works and inventions. For example, it was found that computer programmers voluntarily contribute to open-source projects because of identification with a group, pragmatic motivation to improve one's software or career, social and political motivation to support a movement, and enjoyment derived from the process itself (Hertel et al. 2003).

Exceptions and Limitations to Intellectual Property Rights

Although propertization through intellectual property rights is the preferred method of solving the market failure in information problem, it on the other hand creates a different form of market

failure, i.e., monopoly from exclusive right. In order to contain and limit the ill effects of monopoly power from intellectual property rights, various legal strategies are used, some of which are discussed below.

The first strategy is to control the breath of the intellectual property rights, i.e., the extent it could prevent other similar creations from being lawfully used. Limiting the breath of protection will facilitate competitors' ability to produce close but differentiated substitutes in the marketplace and thereby foster a market characterized by monopolistic competition (Chamberlin 1933) or imperfect competition (Robinson 1933). For example, copyright law protects expressions and not ideas. So general ideas of fictional stories are not protected, and authors may write fictional stories of the same genres as long as the detailed plots and character names are not colorably similar. Similarly, different publishers may produce their own language dictionaries containing substantially similar word list but with their own definitions.

The second strategy is to limit the term or duration of protection. Almost all forms of intellectual property rights, except for trademarks and confidential information, have limited term of protection. Limiting the term of protection has the beneficial effect of curbing the static inefficiency from monopoly power and allows users and other producers to have unlimited use of the intellectual property when it lapses into the public domain upon the expiry of its term (Walterscheid 2000). Although trademarks may be renewed indefinitely, registration may be revoked for non-use, so as to prevent useful trademarks from being hoarded by first-moving trademark owners. Undisclosed confidential information gets protection so long as the information is kept secret and not disclosed to the public. It loses protection immediately when an independent party rediscovers the confidential information through independent effort or through reverse-engineering of a publicly available product.

The third strategy is to create situational exceptions to protection. An economic justification for such an exception is that the transaction cost of licensing for the use of the intellectual property would outweigh the benefit of using the

intellectual property. Potential users will be deterred from using an intellectual property if the only legal route is through licensing. Example of such an exception can be found in copyright's fair use doctrine (Gordon 1982; Gordon 2002). In jurisdictions with statutory exceptions in copyright law, situational exceptions for disadvantaged groups such as the accessibility exception for the disabled can be justified on the ground that not all publishers are willing or interested in selling products which caters to a small market, and thus allowing the disabled to use technological solutions, such as text-to-speech software, to solve their accessibility problem is socially desirable.

The fourth strategy is to allow compulsory licensing in exceptional circumstances. Compulsory licensing can be seen as a form of liability rule protection of intellectual property rights (Reichman 2009). When compulsory licensing is evoked, the intellectual property owner has no power to set the price but has to instead accept the price set by an authoritative body, which in some circumstances is below a monopoly price. It also dispenses with the potentially protracted negotiation process in a national emergency. Compulsory licensing provision can be found in patent law which allows the state to manufacture essential medicines when patent holders refuse to grant a license at a reasonable price. Despite its unpopularity, compulsory licensing is rarely used and most often acts as a threat to force patent holders to lower their price of medicine.

Economic Justifications as a Yardstick

Assuming that the proper justification for intellectual property rights is economic in nature, i.e., to solve a market failure problem, then this economic justification can also be used as a yardstick to assess whether new forms of information should be conferred an intellectual property rights protection.

Certain countries and communities are pressing the World Intellectual Property Organization (WIPO) to recognize and protect traditional

knowledge. Unlike patent which protects only new inventions, traditional knowledge protection, as currently defined by WIPO, protects "knowledge, know-how, skills and practices that are developed, sustained and passed on from generation to generation within a community" (Matsui 2015). It appears that since traditional knowledge has been around the relevant communities for a long time, it would not be capable of patent protection because it would not satisfy the novelty requirement of patent law. The fact that traditional knowledge already exists means that there is no lack of an incentive to create problem. Instead the usual justification for protecting traditional knowledge is to reward or compensate the community for developing and preserving the traditional knowledge. However, this justification is actually of a distributional concern and not of an efficiency concern. In other words, traditional knowledge protection is merely a mechanism to transfer some wealth from an often wealthy first-world exploiter to a usually, but not necessarily, poorer and less-developed community.

Another application of the economic justification can be seen in assessing the arguments for retroactive extension of intellectual property term. Opponents of retroactive term extension argue that since retroactive term extension does not incentivize the creation of new intellectual property, it is not a good legal policy as it contradicts the basis for intellectual property rights which is to solve the market failure problem of information (Akerlof et al. 2002).

International Litigation and Arbitration

Abstract

The world of international dispute resolution has changed significantly in the last ten to fifteen years. International actors now must consider a wide array of options regarding

how, when and where their legal disputes will be resolved. This entry discusses the various means of resolving international legal disputes and outlines how law and economics analysis has helped rationalize an increasingly chaotic field of law. In so doing, the discussion considers four core areas of concern: the effectiveness of international dispute resolution; competition between and within different dispute resolution mechanisms; choice of substantive and procedural law and conflict of laws; and third-party funding.

Definition

The field of international dispute resolution is densely populated and includes a variety of types of litigation and arbitration. Not only do these mechanisms differ from each other; they also vary significantly from domestic forms of litigation and arbitration. Scholars must take these distinctions into account if their research is to be credible.

International litigation can refer to the judicial resolution of claims in either national court (sometimes called *transnational litigation*) or international court. An international court may operate regionally (as does the European Court of Human Rights) or globally (as does the International Court of Justice). Disputes heard in international courts are governed by public international law. Although claims arising under public international law may also be heard in national courts, international litigation in national courts typically involves matters of private international law. As a result, international litigation in national courts is often resolved pursuant to domestic legal principles, with the only “international” element arising as a result of the nationalities of the parties.

International commercial arbitration refers to final and binding adjudication of a dispute by a private, neutral decision-maker (i.e., a single arbitrator or a three-person arbitral tribunal). The definition of “international” varies according to national legislation but typically involves parties from different jurisdictions or parties from the

same jurisdiction arbitrating in a foreign country. The definition of “commercial” also varies according to national law, although a number of legal systems simply require some sort of economic effect.

International commercial arbitration is characterized as a “private” form of dispute resolution because it only arises upon the consent of the parties. However, international commercial arbitration also includes a number of public features. For example, the international commercial arbitration regime is built upon an intricate web of international treaties and national legislation designed to support the enforcement of both arbitration agreements and arbitration awards across national borders. These legal instruments have been construed by courts from around the world on numerous occasions, and the data has been collected and published by public and private entities for over 50 years (Strong 2009). The United Nations Commission on International Trade Law (UNCITRAL) is one of the more important public providers, having created a freely accessible online source (CLOUT, or Case Law on UNCITRAL Texts) with a wide variety of national court decisions concerning the various model laws and conventions promulgated by UNCITRAL.

As a matter of practice, international commercial arbitration bears relatively little resemblance to domestic forms of arbitration, including consumer, employment, labor, or final offer arbitration. These latter mechanisms are often extremely informal and typically feature a decreased emphasis on legal authorities and argument. International commercial arbitration, on the other hand, is a very sophisticated and highly legalistic procedure that resembles complex commercial litigation much more than it does domestic arbitration. Awards rendered in international commercial arbitration are usually fully reasoned and are often published in denatured (anonymized) form, thus allowing the international legal community to evaluate and predict arbitral behavior despite the confidentiality of the proceedings themselves (Strong 2009).

Investment arbitration (also referred to as *investor-state arbitration* or *treaty-based arbitration*)

refers to arbitral proceedings that arise pursuant to a bilateral investment treaty (BIT), a multilateral investment treaty (MIT), a free trade agreement (FTA), or an investment protection agreement (IPA). Although *interstate arbitration* (meaning arbitration between two nation-states) may also be initiated under many of these instruments, such proceedings seldom occur. Instead, it is more likely that an individual investor will file proceedings seeking redress from injuries allegedly caused by the actions of the host state.

Investment arbitration can be distinguished from *contract-based arbitration* (which includes both international commercial arbitration and domestic forms of arbitration) in several ways. For example, consent to investment arbitration does not rely on contractual privity between the investor and the respondent state but instead arises as a result of a standing offer of arbitration from the respondent state (as reflected in the relevant treaty or other international agreement) to the individual investor. Investment arbitration also differs from international commercial arbitration in that the former primarily addresses questions of public international law. As a result, investment arbitration has been analogized to international courts in some key regards (Born 2012).

The procedural sophistication and formality of investment arbitration is similar to that of international commercial arbitration. In fact, investment arbitration is sometimes governed by procedural rules originally developed for use in international commercial arbitration. However, the quasi-public nature of investment arbitration has permitted or required the introduction of a number of procedural features not seen in other types of arbitration, including the possibility of third-party participation through the filing of *amicus*-type submissions. The need for transparency in investment arbitration has also led to the routine publication of investment awards, often in their original rather than denatured form. Investment awards are fully reasoned and may include dissenting opinions.

Although litigation and arbitration are the best-known methods of international dispute resolution, *international mediation* has received an increasing amount of attention in recent years in

both the international commercial and investment contexts. The surge of interest in international mediation is somewhat surprising, given the long-standing availability of *international conciliation*. However, international conciliation has never been as popular as international arbitration as a means of resolving cross-border conflicts.

Although considerable debate exists as to whether conciliation and mediation are identical in all regards, scholars agree that both mechanisms are nonbinding (unless and until the parties execute a binding settlement agreement) and cooperative rather than adjudicative. Like arbitration, mediation and conciliation are private dispute resolution mechanisms that arise through the consent of the parties. Although a full analysis of the law and economics literature concerning international mediation and conciliation is beyond the scope of the current discussion, a number of commentators have suggested that mediation and conciliation provide a more effective and cost-efficient means of resolving international disputes (Spain 2010; Welsh and Schneider 2013). Further research in this field would appear to be beneficial and could possibly build on the large and growing number of empirical and economic analyses concerning the efficacy of mediation and settlement in the domestic context. However, future work would need to specifically address the effectiveness of these mechanisms in the international realm.

Another area of inquiry that is not addressed in this entry involves interstate trade disputes, such as those heard by the World Trade Organization (WTO) or arising under certain FTAs. Although law and economics scholars have considered these types of concerns on occasion (Guzman and Simmons 2002; Symposium 2012), these matters are traditionally not considered under the rubric of international litigation or international arbitration *per se*. Instead, these disputes are generally analyzed as a matter of trade law.

Categories of Analysis

Domestic forms of arbitration and litigation have long been subject to analyses based on law and

economics (Benson 2000; Sanchirico 2012). Although some of these studies may be readily transferable to the international setting, caution must be exercised, given the numerous distinctions between international and domestic forms of dispute resolution.

At one time, scholars hesitated to use law and economics to consider international legal concerns (Dunoff and Trachtman 1999). However, the last 15 years has seen a significant increase in economic analyses relating to international law. Some of these studies have focused on institutional concerns, while others have emphasized features relating to the allocation of jurisdictional authority in matters involving regulatory overlap (Guzman 2008a; Trachtman 2008; Danielsen 2011). A significant amount of work has also been done in matters concerning international litigation and arbitration, facilitated, in large part, by the ever-increasing amount of empirical data concerning international dispute resolution (Drahozal 2006; Franck 2007a; Van Harten 2012).

At this point, the law and economics literature on international litigation and arbitration appears to fall into four different categories: effectiveness of international dispute resolution, competition between and within different dispute resolution mechanisms, choice of substantive and procedural law and conflict of laws, and third-party funding for international litigation and arbitration. Each of these matters is addressed separately below.

Effectiveness of International Dispute Resolution

Domestic forms of dispute resolution are typically predicated on assumptions about the coercive power of the state. However, some forms of international dispute resolution involve states as defendants or respondents, thus raising questions about whether, why, and to what extent such mechanisms are effective, given the absence of traditional means of coercion. These issues have been analyzed from several perspectives, including that of rational choice theory (Guzman 2008b), game theory (Ginsburg and McAdams 2004), and behavioral economics (Van Aaken 2014).

The premises of the individual studies can vary significantly. In some cases, researchers evaluate the effectiveness of different international tribunals so as to help improve the design of future international dispute systems and thereby maximize the possibility that the legal system in question will achieve its stated goals. Other scholars study effectiveness in order to identify the limitations of the relevant court or tribunal. In all cases, the ultimate aim is to rationalize a field that has traditionally existed outside the realm of empirical and scientific analysis. When considering these issues, commentators have discussed bodies as diverse as the International Court of Justice, the European Court of Human Rights, the International Tribunal for the Law of the Sea, and various sorts of arbitral tribunals, including those operating under the Convention on the Settlement of Investment Disputes Between States and Nationals of Other States (ICSID Convention).

Competition Between and Within Different Dispute Resolution Mechanisms

International dispute resolution has become increasingly fragmented in the last few decades. Although international courts and tribunals may have exclusive jurisdiction over some types of legal injuries, parties can often bring the same or similar claim in another venue. As a result, questions regarding jurisdiction can be framed in terms of both commons and anticommons.

The existence of jurisdictional choice has resulted in a great deal of competition between and within different dispute resolution mechanisms, which has led to scholars in law and economics to consider these sorts of issues from a variety of perspectives (Ramsmeyer 2000; Trachtman 2008). Perhaps the most extensive work has been done on the relative benefits of international commercial arbitration over international litigation in national courts. One natural area of inquiry involves the question of transaction costs, which in this field can include costs associated with the dispute resolution process itself (often referred to as “litigation costs”) as well as costs associated with negotiation of the underlying dispute resolution provision.

Most scholarship in this field has focused on litigation costs, which makes sense in light of the traditional understanding of international commercial arbitration as a less expensive option than international litigation in national courts. However, the cost-effectiveness of arbitration has recently been called into question, at least with respect to direct costs such as those relating to attorneys' fees and arbitrators' fees. As a result, some observers have suggested that arbitration has lost its competitive advantage over litigation.

Although the increase in direct costs is disturbing to many in the international community, international commercial arbitration may nevertheless retain its superiority over litigation because arbitration allows parties to reap certain indirect benefits. For example, international commercial arbitration is often said to reduce transaction costs and provide a more efficient means of resolving international commercial disputes because it offers more predictability with respect to the forum, procedure, substantive law, and enforceability of the resulting decision (Ramsmeyer 2000; Strong 2014). Although widespread adoption of the Hague Convention on Choice of Court Agreements could apply some pressure with respect to these features, that instrument has not yet come into force. As a result, international litigation does not seem to be closing the gap with arbitration in terms of procedural or substantive predictability.

To the contrary, studies appear to suggest the continuing existence of a "home court advantage" in national courts (Bhattacharya et al. 2007). Furthermore, the law and practice relating to the recognition and enforcement of foreign judgments around the world remains highly unpredictable (Rotem 2010). As a result, the most rational course of action for international commercial actors is to avoid international litigation in either party's national court.

Although this data suggests that international commercial arbitration is preferable to international litigation, law and economics scholars have nevertheless considered whether particular arbitral practices can be improved upon. One area of interest involves the pre-hearing exchange of

documents and information (referred to as either disclosure or discovery). Recent years have seen an increase in the amount of information that parties have sought on a pre-hearing basis. However, economic analysis has suggested a rational actor should prefer the more limited form of document production that characterized early forms of international commercial arbitration rather than the more expansive type of disclosure that is increasingly becoming the norm (Rojas Elgueta 2011).

Some commentators have analyzed arbitral procedures on a more comprehensive basis and have factored in whether and to what extent arbitration is capable of providing ancillary assistance (such as the ability to issue anti-suit injunctions or freeze assets) and increasing the enforceability of the resulting decision (Rutledge 2012). These studies suggest that, rather than adapting to make arbitral procedures more like judicial procedures, international commercial arbitration should retain its distinctiveness so as to retain its competitive advantage. Indeed, some scholars believe the comparative benefits of international commercial arbitration are so significant that arbitration should be made the default position in international commercial disputes (Cuniberti 2009). Some commentators distinguish between the efficiency of international commercial arbitration (Posner 1999; Kovacs 2012) and that of investment arbitration (Franck 2011).

One issue that the literature is addressing with increasing frequency involves the role that dispute resolution mechanisms play in the development of international regulatory law. In many cases, the absence of a single political actor with international regulatory authority has required parties who have suffered multijurisdictional legal injuries to seek relief from national courts. Although some judges have occasionally been willing to fill these sorts of international regulatory gaps, national courts are typically limited in their ability to exercise jurisdiction over foreign parties or apply domestic law extraterritorially (Buxbaum 2006). Furthermore, it can be difficult, if not impossible, for national courts to coordinate their regulatory standards and mechanisms, thereby resulting in market inefficiencies.

Scholarship in this field offers a number of different insights and conclusions. For example, some observers suggest that national courts should be allowed to exert a broad jurisdiction over international regulatory concerns so as to increase efficiency in this area (Mehra 2004). This approach is supported by studies suggesting that private litigants may be particularly efficient enforcers of public regulatory aims in cases involving public goods or commons constellations (Van Aaken 2010). However, other commentators have expressed concern about overgeneralization in this area of law and have suggested that the varying nature of different public goods requires case-by-case analysis (Symposium 2012).

One way to avoid some of the problems associated with regulation via litigation in national courts is through arbitration, since arbitration does not experience the same kinds of problems as litigation does with respect to jurisdiction, enforcement, and application of foreign law (Strong 2013). However, it is unclear whether and to what extent it is appropriate for private tribunals to adjudicate matters of public concern. Some commentators have suggested that questions of public law should be arbitrable in developing but not developed countries, since that approach maximizes economic development and international commercial activity (McConaughay 2001).

Other scholars evaluating regulatory concerns have focused not on the nature of the claim or the quality of the governing law, but instead on the parties themselves. For example, questions have arisen as to whether state actors may be considered proper participants in international commercial (as opposed to international investment) arbitration. Authors approaching the issue from a law and economics perspective have answered that question positively, based on analyses demonstrating that states operate as firm-like economic organizations (Guevera-Bernal 2004).

Although states sometimes appear as parties in international commercial arbitration, they may also be named as respondents in international investment arbitration. Investment arbitration is a risky and costly endeavor, and states and commentators are continually reassessing the

economic value of participating in a treaty regime that exposes them to such a high degree of financial liability (Franck 2007b; Trakman 2012; United Kingdom Department for Business, Innovation and Skills 2013). One of the issues that is constantly under scrutiny is whether and to what extent participation in the investment treaty regime actually increases foreign direct investment in the signatory state (Franck 2007b).

States are not the only parties that must evaluate the value of investment arbitration. Investors who believe that they have suffered a legal injury typically undertake sophisticated cost-benefit analyses to determine whether to pursue a claim in investment arbitration or in another possible forum (Bjorklund 2007). Empirical and economic studies help investors make these decisions by illuminating the likelihood of success in a particular venue (Franck 2007a) and the costs associated with seeking a certain type of legal redress (Franck 2011).

Competition not only exists between different types of international dispute resolution, it also exists within each category of procedures. For example, arbitral institutions from around the world are constantly working to optimize their attractiveness to prospective parties and distinguishing themselves from competitor organizations (Dezalay and Garth 1995; Drahozal 2000a; Ramsmeier 2000; Choi 2003; Rogers 2006). In so doing, arbitral institutions must identify those procedural trends that should be followed and those procedural innovations that should be resisted. Arbitral institutions are now able to differentiate themselves in a variety of ways, ranging from transparency of proceedings to the availability of expedited procedures. Economic analyses consider not only whether and to what extent individual innovations improve the efficiency of the arbitral process but also how external market forces drive competition between the different organizations.

Competition also exists between individual cities and countries that want to position themselves as potential seats for arbitration. Rent-seeking lawyers may undertake a variety of efforts to position their city or state favorably vis-à-vis any actual or perceived competitors (Drahozal 2000a,

2004; O'Connor and Rutledge 2014). Economic analyses in this area consider the effectiveness of these various means of attracting arbitration business to a particular region, including standardization versus innovation in the national arbitration law, improvement of judicial procedures relating to arbitration, liberalization of the underlying substantive law, and relaxation of rules regarding the unauthorized practice of law.

Competition also exists with respect to individual arbitrators seeking to be named to various public or private tribunals (Dezalay and Garth 1995; Drahozal 2000a; Rogers 2005, 2006; Franck 2009). Commentators have suggested that informational imperfections regarding the qualifications and availability of potential arbitrators and the performance of arbitrators create numerous inefficiencies in the process of selecting arbitrators. Furthermore, the market for international arbitrators appears to reflect a number of barriers to entry. Indeed, empirical research clearly demonstrates that the market for international arbitrators is extremely constrained in terms of age, nationality, race, gender, education, and professional qualifications.

Choice of Law and Conflict of Laws

Another area of inquiry that has benefitted from the application of economic analysis involves choice of law in international disputes. A number of studies focus on issues of substantive law, based on the premise that substantive inefficiencies have a detrimental effect on global economic welfare (Drahozal 2000a; Rühl 2006; Whytock 2009; Ller 2011; O'Connor and Rutledge 2014). When testing this hypothesis, some researchers focus on the relative benefits of different national laws and non-state law, such as the International Institute for the Unification of Private Law (UNIDROIT) Principles of International Commercial Contracts and the United Nations Commission on International Trade Law (UNCITRAL) Convention on the International Sale of Goods (CISG), while other commentators consider the transactional costs associated with creating individualized contracts relating to choice of law. Other analyses look at state-imposed conflict of laws rules to determine

whether and to what extent these default regimes can be considered either efficient or reflective of the parties' presumed intent. In each of these cases, the methodological approach and motivating principles are similar to those seen in studies of the domestic law market, although the analysis is much more challenging at the international level, since the relatively high degree of substantive and procedural autonomy associated with international dispute resolution increases the number of variables that must be considered.

One area of particular interest to law and economics scholars is the *lex mercatoria*, also known as the international law merchant. The *lex mercatoria* is said to embody certain customary international legal norms concerning trade practices and usages and therefore provides various insights into the nature of contract law and corporations (Symposium 2004; Oman 2005). Other studies have focused on whether and to what extent arbitrators actually rely on the *lex mercatoria* and have often concluded that this body of law is applied much less frequently in practice than in theory (Drahozal 2000a; Symposium 2004).

Although most studies relating to substantive choice of law are global in nature, some focus on the particular pressures that arise within the European Union as a result of regional integration of certain political and economic matters (Watt 2003; Michaels and Jansen 2006). Specialists in European law have also considered the extent to which US-style law and economics theory has really taken hold in European legal thinking regarding conflict of laws questions and have concluded, contrary to certain conventional wisdom, that there is indeed evidence of a cross-Atlantic jurisprudential dialogue (Nicola 2008).

Although the literature on law and economics is rife with discussions relating to choice of substantive law, procedural choice of law is also an issue of interest in the field. Thus, a number of studies consider the transaction costs associated with customizing arbitration provisions (Choi 2003) or litigation procedures (Drahozal and O'Connor 2014; Hoffman 2014; Strong 2014). Although parties often have a great deal of scope in which to exercise their procedural autonomy,

several of these studies suggest that parties seldom do so, preferring instead to rely on default provisions established as a matter of state law or arbitral custom.

Other inquiries focus more on systemic issues. Thus, some commentators consider the economic benefits associated with procedural harmonization across national boundaries (Visscher 2012), while other observers focus on questions relating to why procedures promoting settlement are present in some jurisdictions but absent in others (Cortés 2013). These types of analyses may be of particular relevance to legislators seeking to improve the design of their national dispute resolution regimes.

Legislators may also be interested in studies focusing on the efficacy of specific rules of procedure. Thus, economic analyses have been applied to questions involving the exercise of extraterritorial jurisdiction (Trachtman 2001, 2008), enforcement of foreign judgments (Rotem 2010; Rühl 2006), and enforcement of foreign arbitral awards (Drahozal 2000b). These studies are quite diverse in nature and consider everything from the role of externalities in the decision-making process and how international jurisdiction is both a commons and an anticommons to the role of informational asymmetries and general issues relating to regulatory competition. However, some critics contend that law and economics is not the proper lens through which to view problems of international procedure (Kessedjian 2005).

The literature also encompasses a number of macro-level analyses, such as those considering the differences, if any, between hard and soft forms of international law (Shaffer and Pollack 2010) and between the common law and civil law traditions (Mattei 1997; Parisi 2002; Arruñada and Andonova 2008). These studies can be useful in determining the cost-effectiveness of various types of reform, both as a substantive and procedural matter.

Third-Party Funding

As international dispute resolution has become more expensive, parties and legal systems have begun to explore alternate ways of funding the

various proceedings. One particularly intriguing mechanism involves third-party funding, which is sometimes referred to as “third-party litigation funding.” This device involves an unaffiliated entity choosing to pay for the legal costs of one of the parties in exchange for a certain percentage of the final award. Third-party funding has been used in both litigation and arbitration and is coming under increased economic scrutiny. Some studies are comparative in nature (Barker 2012), whereas others are either national (Hylton 2012) or international (Steinitz 2011) in scope. Few conclusions have yet been reached, since the mechanism is still in its early stages, but early analyses suggest that third-party funding will fundamentally change the economics of dispute resolution.

Internet Governance

Philip C. Hanke

Department of Public Law, University of Bern, Bern, Switzerland

Abstract

The Internet is not regulated by a central authority, but instead by a plethora of institutions involving numerous stakeholders. Internet governance can be understood as a field that not only pertains to infrastructure regulation, but also to other legal questions such as copyright, hate speech, cyber-bullying, data protection, and others.

Definition

Internet governance, according to the UN-initiated World Summit on the Information Society, is “the development and application by Governments, the private sector and civil society, in their respective roles, of shared principles, norms, rules, decision-making procedures, and programmes that shape the evolution and use of the Internet” (“Report of the Working Group on Internet Governance” 2005).

Introduction

The Internet is a globally distributed network constituting a patchwork of interconnected autonomous networks. As such, there is no centralized governing body overseeing it. However, a governance structure is necessary for coordination and the assignment of certain property rights (e.g., domain names and Internet Protocol addresses). One early characterization of Internet governance identified three layers of regulation: the physical infrastructure layer contains the hardware, the logical layer contains the software, and the content layer contains the transmitted information. Each layer comes with its own questions, such as network access, copyright issues, or monetization (Benkler 2000).

The Internet, in a way, can be considered a public good (Spar 1999). Consumption is basically non-rivalrous. Although congestion can be an issue with increasing usage, its infrastructure is highly scalable and expandable almost without limits. The Internet also fulfills the second requirement of public goods, namely, that users cannot be excluded from accessing it. Certain services (e.g., access through specific Internet providers) are excludable, but the architecture as a whole is not.

Despite its characteristic as a public good, it has nevertheless successfully transferred into the private sector over the last 20 years. Although it first developed at universities and government agencies, the infrastructure, and arguable most of its content, is provided by private companies.

A Brief History of Internet Governance

The Internet as it is known today evolved from several precursor networks. One important network was ARPANET, developed and funded by the Advanced Research Projects Agency (ARPA) of the US Department of Defense (DoD) and established in 1969. In 1981, it was expanded by the National Science Foundation's Computer Science Network to connect its supercomputing facilities, research networks, and university campus networks. Since 1982, ARPANET has used the TCP/IP protocol suite, which is the cornerstone of modern Internet infrastructure. Throughout the 1980s, other countries were connected to ARPANET/NSFNET. In the 1990s, the network became the Internet: ARPANET was terminated in 1990, and the NSF started to first allow commercial usages of NSFNET in 1991, lifting the final restrictions in 1995. The NSF ended its sponsorship of the backbone services, and the private sector took over the provision of infrastructure. An originally state-owned network had thus become a mainly private network regulated by standards and commercial agreements (for a historical overview, see, e.g., Abbate 2000; Ryan 2013). Certain legacies from the Internet's early era, such as the role of the US government, survived until very recently.

Who Governs the Internet?

The operation of the Internet requires certain administrative tasks, such as assigning domain names (e.g., [google.com](https://www.google.com)), IP addresses (e.g., 216.58.214.110 is an IP address that the domain name [google.com](https://www.google.com) points to – however, a large website like Google operates many servers around the globe and thus uses many IP addresses for their different services), and other parameters. This assignment of names and numbers is overseen by the nonprofit Internet Corporation for Assigned Names and Numbers (ICANN) based in Los Angeles, California. ICANN, in turn, is managed by an International Board of Directors representing the constituencies of ICANN, its Supporting Organizations (the Generic Names Supporting Organization, the Country Code Names Supporting Organization, and the Address Supporting Organization), and its subgroups. Governments enter the structure through the Governmental Advisory Committee, which has an advisory role.

The Internet's domain name system (i.e., the list that assigns domain names to IP numbers) is administered by the Internet Assigned Numbers Authority (IANA), managed by ICANN. Until 2016, the US Department of Commerce (DoC) could overrule any resolution made by that body. This special role of the US government was a contentious issue for a long time, and handing over full control over IANA to ICANN was an important step in fully transition Internet governance toward a fully multi-lateral, international system.

An important forum to develop Internet governance is the Internet Governance Forum (IGF). It was established in 2006 by the secretary-general of the United Nations and holds annual meetings. Its main institutional bodies are the Multi-stakeholder Advisory Group (MAG) and the Secretariat based in Geneva, Switzerland. The MAG currently consists of 55 members representing governments, private industry, civil society, academia, and technical communities. Membership is not permanent but instead rotates regularly, and the UN secretary-general has the final say in the selection process initiated by the undersecretary-general for Economic and Social Affairs.

The standardization of the Internet's core protocols takes place under the auspices of the Internet Society (an NGO founded in 1992 and based in Reston, Virginia, and Geneva, Switzerland), more specifically mainly within the Internet Engineering Task Force, an open standards organization run by volunteers (whose work is usually funded by their employers). It also serves the host institution for the Internet Architecture Board (a committee of the IETF), the Internet Engineering Steering Group (a committee responsible for the technical management of IETF activities), and the Internet Research Task Force (focused on longer-term research issues related to the Internet).

Standards relating to the World Wide Web, that is, the part of the Internet that is accessed through the hypertext transfer protocol (HTTP) using a web browser, are set by World Wide Web Consortium (W3C). The Consortium has well over 400 members, including NGOs, private businesses, academic institutions, governmental entities, and some private individuals. Membership is subject to fulfilling certain requirements and receiving the approval of the existing members.

Thus, Internet governance is a patchwork, and proposals for reform to construct a coherent regime have been made since the mid-1990s. A global framework, for example, through a convention, was discussed in the academic debate but did not find momentum at the policy level (see, e.g., Mueller et al. 2007; Weber 2014).

Contentious Issues

The view that the Internet is a border-free network, free from territoriality, and thus controlled by governments is, however, contested. It has been argued that in many Internet-related policy fields – such as e-commerce, privacy, speech and pornography, intellectual property, and cybercrime – national governments do play a dominant role in regulation (Goldsmith and Wu 2006).

Occasionally, big decisions regarding the infrastructure arise. One large issue was a change in the length of Internet Protocol (IP) addresses, that is, the unique numbers required to identify machines on the Internet to be able to exchange information. The original system (IPv4) allowed for 4.3 billion

addresses, which is not enough for modern uses of the Internet. Although a new standard – IPv6, allowing for 340 undecillion addresses (36 zeros) – was selected already in the 1990s, the conversion process is still ongoing, which has to do with a nonobvious yet present political process taking place in the background (DeNardis 2009). The interconnectedness between infrastructure standard setting and broader, more political questions such as openness and transparency can thus make fairly straightforward decisions like increasing the number of IP addresses more difficult.

Another highly contested issue in terms of infrastructure is net neutrality, that is, the principle that Internet service providers (ISPs) and regulatory agency should treat all data on the Internet the same – the Internet equivalent of the common carrier principle in common law countries and the public carrier principle in civil law countries. In the European Union, Art. 3(3) of EU Regulation 2015/2120 requires ISPs to “treat all traffic equally, when providing Internet access services, without discrimination, restriction or interference, and irrespective of the sender and receiver, the content accessed or distributed, the applications or services used or provided, or the terminal equipment used.” Some EU member states also have national laws ensuring net neutrality. In the United States, net neutrality has been the object of many years of lobbying. In 2015, the Federal Communications Commission set forth rules protecting the equal treatment of Internet traffic, mainly by classifying broadband as a common carrier. However, it is possible that these rules change again under the Trump administration. The policy of mandated net neutrality is highly controversial: while it is defended on the grounds that it protects consumers by keeping access to the Internet equal to all and is important for innovation (Lee and Wu 2009), some economists criticize and see it as price regulation hindering competition (Hahn and Wallsten 2006; Becker et al. 2010; see in particular Maillé et al. 2012 for an overview of the debate).

Conclusion

A narrow definition of Internet governance would solely address questions of Internet infrastructure.

However, a broader view would encompass aspects of policing contents delivered through the Internet and thus include problems such as cyberbullying, copyright law, data protection rules, as well as safety-related matters.

Traditional approaches based on the principles of state sovereignty and clearly defined territoriality would fail to address the inherent problem of providing and maintaining a decentrally provided public good. Besides questions of infrastructure, activities such as hate speech or copyright infringement lead to strong interjurisdictional externalities. As a result, Internet governance is an archetypical example of highly decentralized, multilayered, transnational, public-private governance. Many important institutions for standard setting (such as the IETF) remain rather informal organizations and show a certain degree of ad hocism. Functionally, there is a lot of overlap between infrastructure design, public policy, and education in the activities of the involved institutions. With increasing digitalization and reliance on the Internet, contested questions regarding Internet governance gain relevance as the latter determines Internet freedom and as a result increasingly freedom of society in general (DeNardis 2014).

Abstract

The question of human motivation is central to understand the effects of legal rules on people's behavior. One of the main tenets of law and economics is that incentive systems need to be

designed in order to minimize the difference between private and social interests. Legal rules, taxes, subventions, and other external interventions are regarded as necessary to motivate the internalization of externalities. Empirical evidence however suggests that motivation to engage in pro-social behavior may preexist to external incentives. People often avoid cheating, polluting, or littering, and they act pro-socially without considering consequences of deviation to do so. The traditional idea of “laws as price incentives” has a difficult time explaining these phenomena. This is why in the last two decades, one of the most promising research agenda consisted in distinguishing between “extrinsic” and “intrinsic” motivations. The former are linked to actions driven by external incentives, in contrast to the latter driven by personal and internal forces.

Synonyms

External incentives; Internal motivations; Self-interest; Social preferences

Definition

Intrinsic motivation was originally defined as some inherent interest in a task, which cannot be derived from the agent’s economic environment. As such, intrinsically motivated behaviors aim at bringing about certain internal rewarding consequences independent of any extrinsic rewards. With the multiplication of experimental results displaying high levels of cooperation when monetary and social sanctions are inoperative, intrinsic motivation has come to be viewed as a natural response to the idea that socially desirable conduct can solely be motivated by economic incentives. The overarching idea is that because individuals have intrinsic motivations to behave pro-socially, extrinsic incentives such as promises of reward or threats of punishment were not always needed, and, under some conditions, it is desirable to rely on intrinsic motivation alone.

Incentives and Motivations

Selfish decisions, made by one person, can have very bad consequences for other people and society at large. Law and economics refers to this problem as “social costs” (Coase 1960) or “externalities.” Thus, it is important to temper individual selfishness to guarantee both: the functioning of the market, which rests on the respect of property rights, and the advancement of social welfare that rides on the provision of public goods. How can we discourage *socially* costly behaviors and encourage people to contribute time and money to the public interest? This question lies at the heart of the “new law and economics” (Kornhauser 1988). This strand of literature suggests that law can create material incentives, such as sanctions or rewards, for even the most selfish individuals to think twice before engaging in socially undesirable conduct. For example, tort law creates such external incentives through the determination of damages the injurer has to pay for the harm caused. This should deter potential injurers from harming others.

However, the limited and sometimes counter effects of external incentives on pro-social behavior are increasingly pointed out by psychologists (Deci and Flaste 1995) and economists (Frey 1992, 1997a, b). And the notion is gaining popularity within the law and economics community (Bohnet et al. 2001; Bohnet and Cooter 2003; Feldman 2009). The idea is that motivation is in fact dual, composed of an intrinsic element besides an extrinsic one.

Intrinsic motivation was originally defined as some inherent interest in a task (Deci 1971). However, it has long since been expanded to include: environmental morale (Frey and Stutzer 2008), civic duty (Frey et al. 1996), fairness and reciprocity (Fehr and Schmidt 1999), and potentially other pro-social unselfish motivations such as “conscience” (Stout 2011).

One of the major insights from this strand of literature is that trying to minimize the difference between individual and social interests by external incentives may actually undermine intrinsic motivation (Gneezy and Rustichini 2000; Bénabou and Tirole 2003). The two types of

Intrinsic and Extrinsic Motivation, Fig. 1

The interactions between external incentives and intrinsic motivation in increasing pro-social behavior

motivations are effectively interacting to produce the final behavioral response. This is called the inseparability thesis (Bowles 2011). Figure 1 illustrates the relationship among these variables, with the positive and negative signs indicating the direction of the effect.

At the core of the interrelationship between intrinsic and extrinsic motivations are the notions of *competence* and *autonomy* (Ryan and Deci 2000; Tirole 2009; Festré and Garrouste 2014). The prescriptive character of rewards and sanctions, such as imposed by the legal system, may indeed undermine people's confidence in their capacities to voluntarily restraint from undesirable conduct (Bénabou and Tirole 2003) and reduce their sense of autonomy by shifting the locus of control from inside to outside the person (Ryan and Deci 2000). Whether this substitution effect exists and to what extent it plays a part in people's reactions to external incentives is a debated empirical question to which we turn next.

Empirical Tests of Motivation Crowding (Out)

Research on the "crowding-out" effects of extrinsic incentives on people's intrinsic motivations can be divided into two groups. The first group focuses on the effects of rewards and sanctions on people's decision to engage in pro-social behavior. The second strand of literature takes other compliance instruments, which are generally labeled as "control" strategies, and attempts to shed light on their capacity to encourage desired conduct.

The Effects of Material Incentives

Contrary to economic theory's postulate that people supply more of a good or service when its

price goes up (holding all other prices constant), Titmuss's (1970) empirical investigation of blood donations in the United States of America and Great Britain indicates that paying people in return for their blood might decrease altruistic blood donations. The explanation being that under this monetary incentive, donors no longer consider their act as an altruistic blood donation but as an economic transaction. Following this puzzling idea, Frey et al. (1996) designed a field experiment to test the effects of monetary incentives on Swiss households' acceptance of a nuclear waste recycling plant in their neighborhood. They found that tangible rewards decrease acceptance due to the crowding-out of "public spirit." Along similar lines, Fehr and Rockenbach (2003) suggest that when people attribute their chosen behavior to external sanctions, they discount any altruistic motivations. Curiously, in their game, the amount of cooperation is higher in the absence of the sanction for noncooperative behavior. This is congruent with Bohnet et al. (2001) findings that provisions with respect to contract enforcement may crowd-out trustworthiness and negatively impact performance. In addition, an important aspect of this literature is that external incentives' detrimental effects on cooperation are nonmonotonic. In the case of contract enforcement, performance rates are high when the expected cost of breach is sufficiently large, decreasing for medium-sized expected sanctions and increasing again for sufficiently small ones. With respect to rewards for performance, there is a discontinuity at the zero payment in the effect of monetary incentives: "for all positive but small enough compensations, there is a reduction in performance as compared with the zero compensation, or, better, with the lack of any mention of compensation" (Gneezy and Rustichini 2000, p. 802). Another important

component of the crowding-out theory suggests that people do not really care about the outcome of a pro-social behavior per se, but instead care about how their behavior is perceived by others – they like to be perceived as fair (Andreoni and Bernheim 2009). Their behavior is thus driven by “image motivation” (Ariely et al. 2009). Within this perspective, extrinsic incentives have a detrimental effect on pro-social behavior due to the crowding-out of image motivation. Finally, Irlenbusch and Sliwka (2005) have shown that once a monetary incentive mechanism is introduced, its detrimental effect persists even after its removal and it spreads out to other areas by altering people’s cognition of the situation.

The Effects of Control

Another central tenet of economic theory, which is at the core of many law and economics models, is that monitoring improves agents’ performance. The legal system often specifies in advance what type of conduct is admissible and the conditions under which it may be carried out. However, the postulate that monitoring is always performance enhancing is jeopardized by experimental results. For instance, Falk and Kosfeld (2006) designed a principal-agent game in which the principal could specify in advance a minimum effort requirement for the agent to put in. Curiously, they found that “the decision to control significantly reduces the agents’ willingness to act in the principal’s interests” (p. 1611). Agents dislike control because it signals principal’s distrust in their capacities to perform a task. Agents “seem to believe that principals who control expect to receive less than those who don’t, and (...) agents’ beliefs correlate positively with their behavior” (p. 1612). This result is not confined to laboratory experiments. In an econometric study of 116 managers in medium-sized Dutch firms, Barkema (1995) showed that increases in personal control by superiors resulted in a significant reduction in the number of hours worked.

Finally, prescribing in detail a particular behavior through ex ante regulations has been found more detrimental than intervening ex post by sanctioning (rewarding) the undesired (desired) conduct. Motivation effects are indeed an

important aspect to be considered in the tradeoff between ex ante state control and ex post legal intervention. The legal system is less likely to reduce people’s sense of autonomy.

Judicial Decision-Making

Alessandro Melcarne
EconomiX, CNRS and Université Paris Nanterre,
Nanterre, France

Definition

Judges are not only the guardians of Human Rights and the Rule of Law. Justices equally play a key role in keeping legal certainty, thus providing a fertile ground for economic transactions. Nonetheless, scholars have only in the last two decades started to openly enquire judicial activity with the lenses of economic analysis. Claiming that judges might be sensitive to certain incentives does not necessarily undermine their independence. However, understanding the economics of judicial decisions is a key to properly

design an institutional framework that might incentivize their work efficiently.

Judicial Decisions and the Economy

A growing economy and sustainable development crucially depend on the functioning of judicial systems. Enforcing institutions have been proven to be fundamental for allowing the reduction of transaction costs and the protection of property rights (Acemoglu et al. 2001; Glaeser et al. 2004; La Porta et al. 1998). Judicial institutions and organizations thus play a fundamental role in the functioning of modern markets. Judges intervene in all litigated economic transactions assuming the role of the impartial “third party” among litigants. However, sometimes the impact of judges’ work might go beyond the mere sphere of interest of the litigants involved in a specific lawsuit. For example, in the case of “blockbuster” class-action cases, the consequences of judges’ decisions might have profound repercussions on society as a whole. Some other times, judicial actors are even called to intervene in the political arena and their behavior might have consequences even for the election of a country’s president (for example, the US Supreme Court in *Bush v. Gore*, 531 U.S. 98).

Despite the relevance of judicial decision-making, economic literature has relatively overlooked this topic. Until recently, few scholars

have tried to shift the rational choice model proper of the *homo-oeconomicus* to judges and their behavior. On the one side, Public Choice literature has focused its attention mainly on legislators and bureaucrats, failing to recognize the public relevance of judicial actors. On the other, legal scholarship has been very skeptical with respect to the idea of conceiving judges with a task that goes beyond the mere mechanical application of the law. According to the “legal formalist” tradition, judges are operating in a sort of *legal empyrean* while isolated from any form of mundane temptation (Melcarne 2017). However, even legal scholars who theoretically do not rule out the idea of interpreting judicial decision-making through the lens of a rational choice enquiry, discard this hypothesis in practice on institutional grounds (Epstein 1990; Epstein and Knight 1997; Heise 2002; Schauer 2000). In this perspective, the overall institutional framework, that we might informally define as judicial independence, has nowadays successfully isolated judges from any sort of “economic” incentive. According to this stream of literature, judicial behavior might be defined within a principal-agent relationship. Within this situation, judges play the role of agents, while the principal would be played, depending on the situation, by litigants, magistrates holding higher positions within the judiciary, politicians, or society as a whole. However, what really matters here is the fact that a relevant share of judges’ activity is characterized by asymmetric information. In this condition, there could be potential grounds for opportunistic behavior on the side of who has greater knowledge. In order to prevent similar circumstances, rules have been designed so to insulate judges from “outside economic incentives” and thus guarantee the credibility and impartiality of judicial enforcement. In this respect, judges are not allowed to accept any form of payment (i.e., bribes) from litigants and not allowed to be involved in extra-judiciary occupations (with some limits). All these institutional arrangements put together are a tool to preserve the genuineness of judges’ work with respect to those that appear before them: being an effective and impartial third-party when solving disputes. In this sense,

it becomes much harder for a judge to cheat and favor someone against what the law prescribes. As a consequence, judicial behavior is correctly determined by the law, as the orthodox view claims, thus leaving insignificant scope for a rational choice enquiry of judges’ actions.

Judges as Utility Maximizers

However, as strict as conduct rules and principal’s control might be, judicial decision-making does never collapses to a mere automatic application of a legal abstract rule to a practical case. A certain degree of freedom (thus discretion) is left to judges’ action; the scope of judges’ autonomy will, at least on a theoretical level, supply ground for their behavior to pursue self-interest and thus be the object of economic analysis (Posner 1993). What might be claimed is that, if judges maximize their utility just as anybody else, the institutional environment in which they have to operate them makes such optimization problem as a “constrained” one (Cass 1995).

Posner (1993) elegantly compares judicial behavior to the act of voting. People vote despite the fact that their individual vote will be marginally irrelevant. In the case of judges, their behavior is very relevant at least for the litigants that appear before them: sometimes, for a vast multitude in the case of courts of last resort. So just as voters extract utility from their votes, the same might be thought for judges. In the act of judging, many objectives might interact with decisions: leisure, reputation, promotion prospects. All these objectives are not strictly in contrast with the institutional design, so are left open to a rational choice individual to be pursued. The degree to which judges will be able to operate rationally, pursuing their personal interests, will depend on how strict the institutional setting is. This will ultimately vary to a great extent not only among different countries and their judiciaries, but also within the same national system, according to the jurisdiction and the hierarchy: the career concerns that might influence judicial decisions are different if considering a trial court judge or one sitting in a court of last resort.

Before Posner (1993), although with some exceptions (Cohen 1991; Cooter 1983; Higgins and Rubin 1980), the general sentiment declined the possibility of shifting economics tools to the investigation of judicial behavior. Scholars considered the overall institutional system granted by judicial independence sufficient to isolate judges from self-interest motivation in their work. Even works that explicitly deal with a formal model of judges' utility maximization (Cooter 1983), do so only with respect to "private" judges, that is, arbitrators. Similar works rule out *ex ante* the possibility that "public" judges (those belonging ordinarily to the judiciary) might behave according to their individual interest. It was only with the sentencing guidelines that studies were able to empirically address this issue (Cohen 1991; Taha 2004). The variance in the way this issue was disposed by judges across the USA allows inferring that it might be due more to judges' incentives, rather than exclusively to legal issues.

The isolation granted by the institutional setting, on the one side limits judges from seeking goals that will undermine the credibility of their impartiality. At the same time, however, such isolation endows judges with a position of advantage to exploit their discretion towards goals that, even if not illegal, might not be considered as strictly related to their duties (career, leisure). The degree of independence they enjoy will determine how binding are the institutional constraints, but the final objective will remain untouched: maximize their utility function. Ambitions are intrinsic in human action: if it is true that judges cannot directly increase their wage by means of their decisions (of course without considering illegal forms of bribing and corruption), there are other potential determinants of their utility functions that might equally bind and determine their decisional processes. In this sense, the research for promotion to higher ranks of the judiciary is even (indirectly) a way for judges to increase their income Melcarne and Ramello (2015). The utility maximization process embedded into judicial decision-making must not necessarily be related to morally doubtful or illegal behaviors. One might think, for example, to the imposition of a specific legal ideal through

judicial decisions, the egoistic use of judicial decision-making as a tool for reputation-building or, sometimes, other rather deplorable judicial behavior as corruption or more in general, the bias of the law from the general interest to a specific one. On the contrary, we might be thinking of much more mundane issues as shirking at the expenses of others' work. In the end, because of the independence enjoyed by members of the judiciary, they are not constrained in the achievement of specific performance goals. At the same time, judges are always free to calibrate their effort according to their career goals (when a career prospect is available) or to their leisure preferences.

Institutions, Incentives, and Judicial Behavior

Every judge is characterized by a peculiar utility function that might vary to different extents from that of an ordinary person. The determinants are probably the same (income, leisure, work satisfaction, reputation), although weighted differently. In general, one might assume that, given the general systems of incentives characterizing judicial systems, the average judge will be characterized by more risk-aversion than a fellow law graduate about to enter legal practice (Posner 2005). Accordingly, judges derive more utility from leisure and public recognition relatively to income. This is because judges' remuneration will not (strictly) depend on their marginal productivity, at least in the short run. Their salary cannot be lowered and they cannot be removed from their job. But indeed this does not exclude the fact that even these individuals might be characterized by a peculiar utility function, more or less constrained by the institutional environment, which they are willing to maximize for their personal well-being.

The main idea of the rational-choice model is that judges are intrinsically self-interested, but the concrete way through which such self-interest manifests itself will depend and vary in intensity according to the institutional framework. This is where differences in judicial systems across countries and even within the same judiciary might affect the study of judges' decisional processes.

The first macro-difference to be considered is the one between career-judiciaries (basically, most of civil law jurisdictions) and those following the Anglo-American model, i.e., recognition judiciaries (Garoupa and Ginsburg 2011). Even within the latter, differences emerge between elected judges and tenured judges. In the case of US elected judges, they will be subject to a vast number of incentives in their behavior, much like an elected politician. First of all, they have a time-limited tenure and so their behavior will change while in office. Second, they not only need to attract votes and thus be able to attract public opinion, but they also need to show good performance and focus their attention on those cases that will be more profitable for them in electoral terms. Furthermore, they need to raise money for their campaign from donors: usually lawyers that litigate in courts. The consequence is that elected judges are less independent, thus implying that their behavior is much more predictable than tenured judges. Agency costs are relatively smaller and thus their behavior is more suitable for economic analysis. Nonetheless, even when the institutional setting is so strict, so that judges are effectively insulated from the more canonical career incentives, this model remains relevant for a number of reasons. This will happen, for example, in the case of US federal district judges, since the probability of being chosen from those ranks to be promoted to courts of appeal is rather low but yet not equal to zero. Furthermore, judges are selected at a relatively older age, after they have already served as practicing lawyers. An environment characterized by such institutional constraints will not determine the total absence of judges' utility, but simply redefine its determinants. In a similar situation, judges are well aware that their decision-making will not affect concretely their future career, but still other factors might determine their decisional process, that are unlikely to be detected by efficient punishing mechanisms.

Since judges' work cannot be normally evaluated, it will be hard to assess if judges are exerting the expected effort. Accordingly, leisure will be a potential channel through which they might exploit their informational advantage. It is

predictable that the same person will be relatively less productive when working as a judge rather than as a lawyer, since the system of incentives is different. For this reason, moonlighting activity is generally prohibited, even if some exceptions are tolerated, as for example, teaching or writing books. However, leisure might be considered as a form of income. More leisure, decreases the amount of pecuniary income demanded by judges at a given quality. However, more leisure implies less work being done and thus more judges needed. In this sense, the entire debate on judicial performance might find a theoretical foundation on these grounds. Given the high standards that are adopted in judges' selection processes, the differences in their performance are hardly explainable only as a matter of different innate abilities or as the consequence of differences in the other productive factors of an ideal judicial production function (e.g., less clerks, or administrative staff, or computers). The strict selection is intended exactly to select only the best ones, but given the specific institutional settings that grant independence to judges, they are not any more bounded by the same set of incentives. Given the general ban of moonlighting jobs, if in a judge's utility function leisure has a much bigger space than careerism, this will induce shirking on her side. Since it is so hard, not only to be identified as lazy, and thus as a "cause" of judicial delay, but even to be "punished" when so, a big incentive will push such judges to slow down their activity, but yielding negative externalities for the judicial system and its users.

In this sense, the institutional isolation that judges enjoy might be a double-edged sword. On the one side, it prevents judges from being "bad," but on the other, it does not force them to be "good." A completely independent judiciary could contribute not to the establishment of the Rule of Law but rather to the "Rule of the Judges." Judiciaries must remain responsive towards society and individual judges must grant a certain level of professionalism and quality. One way to limit the possible negative consequences of such discretion is to combine independence institutions with accountability ones. Make judges accountable of their work is to conceive

a complementarity between two different institutional frameworks, trying to balance opposite incentives among judges (Voigt 2008).

Judicial Delay

Elena D’Agostino¹, Emiliano Sironi² and Giuseppe Sobbrìo¹

²Department of Statistical Sciences, Catholic University of Milan, Milan, Italy

Definition

Justice delay is unanimously considered a negative externality both in terms of security and institutional trust (especially when referred to criminal cases) and in terms of economic development (especially when referred to civil cases). Despite several attempts to make systems more efficient have been taken in many countries, it is almost impossible to come to a unanimous solution able to fit different principles, structures, and procedures.

We review the economic literature on this topic, focusing on Gravelle’s (1990) theory and its applications.

Introduction

It is a matter of fact that asking for justice in front of a court of law requires a very long time to get to a verdict in most of European and non-European countries. Justice delay is unanimously considered a negative externality both in terms of security and institutional trust and in terms of economic development. E.g., Jacobi and Shar (2015) pointed out that companies may prefer to breach a loss contract and litigate just to postpone to pay its debts and/or an eventual insolvency. Despite several attempts to make systems more efficient have been taken in many countries, it is almost impossible to come

to a unanimous solution able to fit different principles, structures, and procedures.

The Market for Justice

Economically speaking, every justice system could be interpreted as a market where it is relatively easy to identify a demand (coming from litigants and their lawyers) and a supply (represented by judges, court administrative staff, etc.). This is probably an interesting starting point, well developed in the literature, in order to identify the effects of delay on the demand and the supply of justice. Looking at countries (like Italy) where judicial delay is particularly evident, what emerges is a gap between the demand and the supply sides.

On the demand side, the literature has emphasized the role of lawyers whose main interest is increasing their income. To do so, lawyers push their customers to start new disputes even when the probability of winning is relatively low. Evidence from Italy, a country characterized by strong delay in courts and a high number of lawyers, suggests that this induced demand effect is emphasized when competition among lawyers is higher, that is when the number of lawyers in respect to population is very high (see D'Agostino et al. 2012; Buonanno and Galizzi 2014). Moreover, there is an incentive to come to a dispute even for parties who are unlikely to win whenever legal interest rates are lower than market interest rates (see Marchesi 2007). Reducing the demand of justice, to be intended as the number of new cases filed in front of first instance courts, would have important effects on the justice system as a whole: evidence from Korea shows that lower caseloads would allow first instance judges to spend more effort on each case, improving the quality of their decision and contributing to lower the rate of appeal cases (see Kim and Min 2017).

On the supply side, improper incentive schemes for judges and administrative staff contribute to make more difficult to close disputes within a reasonable time (see Buscaglia and Dakolias 1996; Palumbo and Sette 2006). More in detail, transfers and insufficient numbers of judges combined with the time spent by them in

extrajudicial activities help increase the backlogs of judicial cases (Calvez 2007).

Creating right incentives is not necessarily difficult or expensive: e.g., Melcarne and Ramello (2015) find evidence from different countries that greater independence of judges from politics stimulates competition for professional upgrades, and positively affects court performances. Following a different perspective, Finocchiaro Castro and Guccio (2015) pointed out that inefficiencies and delay could be due not to judge laziness and/or lack of incentives. Focusing on the Italian experience, they find that the lack of managerial ability to manage the increasing demand of new disputes and the backlog damages the system and significantly contributes to determine court inefficiency in Italy (especially in the South of the country).

Furthermore, procedural rules imposing necessary waiting times, settlement attempts, and other actions make it difficult to shorten justice times (see Djankov et al. 2003; for Italy see also Di Vita 2010). An empirical analysis focusing on Belgium and conducted by Bielen et al. (2015) shows that the use of expert assessments has a negative impact on the duration of trials, as well as the number of pleadings. Focusing on Italy, Di Vita (2015) shown that decentralization of legislative production, such as in those sectors regulated by regional laws, has a negative effect on the duration of disputes in front of the regional administrative courts compared to cases where the applicable rules come from the European legislator. Laws could be (relatively) easily changed by reforms of national civil procedural codes, but the experience we have from several attempts made in different countries is that none of them has developed optimal rules and procedures yet. Evidence from Spain rather suggests the 2000 Procedural Law Reform, combined with some important socio-economic factors (like the economic regression), contributed to grow up the number of new civil cases between 1995 and 2010 (see Rosales and Jiménez-Rubio 2017).

If the main reason for judicial delay can be found in an excess of demand, traditional economic theory suggests that an effective policy could be increasing the price to get access to the market (see Vereeck and Muhl 2000). Such a

policy, however, should take into account the peculiarity of the justice system where efficiency must be accompanied by equity.

Gravelle's Theory

Against the conventional wisdom, however, Gravelle (1990) argues that a control based on price does not fit the justice system, but delay is itself a rationing mechanism able to control the demand for justice "until the number of trials demanded by litigants is equal to the capacity of courts."

The starting point of Gravelle's theory is that judicial procedures impose litigants to take decisions in sequence, such that trying to settle their dispute before going in front of a court of law. Gravelle argues that a rationing system based on higher prices does not ensure that litigants will take the right decision. E.g., suppose that litigants are not perfectly informed about the outcome of the dispute in front of a judge and both believe to be likely to win the case: they may prefer to pay a high price (in terms of taxes and other legal costs) to get access to the court instead of reducing their requests and coming to a settlement.

Rather, Gravelle points out that delay imposes a waiting list to litigants. It works as an additional cost able to push litigants to come to a settlement. As a result, the demand for justice should decrease to the sustainable level, that is, the level that the supply is able to cover.

D'Agostino et al. (2013) find empirical support to the Gravelle's theory testing the trend of appeals in Italy for ordinary, labor and social welfare disputes, separately taken, between 2000 and 2006. The authors find that for ordinary and labor disputes the number of new cases proposed in front of a court of appeal decreases as delay in first instance courts increases.

Conclusion

Judicial delay weakens rights, reduces trust among economic agents, and makes transactions less safe.

All these aspects are considered detrimental for the economic activity and are an obstacle for protecting the rights of citizens and of the economic actors. In this framework, it is difficult to suggest common solutions, because delay in courts is a generalized problem (Dakolias 1999), but with specificities that depend on the legal system of each country and of the type of proceeding (Calvez 2007). In addition to the theory exposed by Gravelle, alternative solutions (applied to general contexts) should be taken into consideration in literature to reduce the length of litigations: first, innovations in administration are possibly correlated with a decrease of the delay in courts. Secondly, an increase in the use of information technology is supposed to improve the efficiency of the justice system. All these possible solutions are effective only if combined with a generalized rationalization of the complexity of court rules.

K

Keeping Promises and Contracts

Sergio Mittlaender

Max Planck Institute for Social Law and Social Policy, Munich, Germany

Abstract

There are reasons for individuals to keep contractual promises beyond legal remedies and reputational concerns. This entry reviews the leading explanations of promise-keeping behavior as well as recent evidence for the latter as collected in laboratory experiments. In the end, it discusses avenues for future research and recent applications of the results collected so far for the design of contracts and their legal enforcement.

Contracts and Promises

Contracts commit individuals to a future course of action. The contractual obligation is created, in common law systems, by the giving of a promise with consideration, and a contract is defined as “a promise or a set of promises for the breach of which the law gives a remedy” (Restatement, Second, of Contracts §1). Promises are therefore an integral part of contracts, and in imposing an obligation for the promisor to perform, or in inducing expectations in the promisee that she

will receive the promised performance, they are apt to motivate promisors to perform just as the legal remedy and reputational concerns do it.

Incentives created by the prospect of payment of damages for breach or by otherwise applicable legal remedies have been extensively studied in the literature (Shavell 1980, 1984). The promisor must anticipate that she will have to bear the cost imposed by the legal remedy if she does not perform, and legal enforcement thereby provides incentives for promisors to perform. Reputational concerns, involving, for instance, the prospect of losing contractual partners and the loss of future gains from trade associated with it, provide another reason for the promisor to make good on her word. They both create material incentives for promisors to perform and not to break their promises. They are, respectively, third- and second-party enforcement mechanisms, executed by the courts and by the promisee.

An individual that has an obligation to perform, and to do what she promised to the other party, might tend to keep her word for non-monetary reasons that operate in the promisor’s internal value system. The promisor might want to comply with the moral norm that promises ought to be kept – or that *pacta sunt servanda* – or she might want to avoid experiencing guilt from letting down the expectations of the promisee. These are the two main reasons why individuals might keep promises – (1) moral obligation and (2) guilt aversion – even in the absence of legal enforcement and reputational concerns.

There is by now substantial evidence that promises, even when they are only cheap talk (Crawford and Sobel 1982; Farrell and Rabin 1996) and their breach does not impose any material consequence on the promise breaker, are often kept at a cost for the promisor. Promises are subject to first-party enforcement, executed by the promisor herself, and are capable of inducing higher average levels of cooperation, trustworthiness, and sharing in games in which the strictly dominant strategy for the promisor is another one, such as in common-pool resources, holdup, trust, and dictator games (Ostrom et al. 1992; Ellingsen and Johannesson 2004; Charness and Dufwenberg 2006, 2011; Vanberg 2008). For sure, not all individuals keep their promises, but many do so, and the question that remains – and that has been subject to theoretical and empirical investigations recently – is *why* they do so.

The empirical evidence reviewed in this entry relies, most often, on the behavior of trustees in a modified version of the trust game originally developed by Berg et al. (1995). In this game, players have a certain endowment (usually \$10), are anonymously matched in pairs, and then are randomly assigned either to the role of a sender or a receiver. The sender (the first mover) can transfer any amount from her endowment to the recipient (the second mover) and keeps the remaining for herself. The amount transferred is multiplied by a factor larger than one (usually, it is double or tripled), which implies that it is socially optimal to transfer everything. The recipient can then freely decide on whether to reciprocate trust and transfer some amount back to the sender or rather keep the money for herself. The game is played only once, anonymously, and its backward-induction solution is, under traditional economic assumptions, unique: the sender must anticipate that the recipient will not repay any money and is therefore predicted not to send to the recipient any amount in the first place.

In reality, senders most often trust recipients and transfer positive amounts, and recipients often reciprocate by transferring back some amount to the sender. Still, around half of the possible gains from cooperation remain unrealized, as first movers transfer, on average,

only around 50% of their endowment (Johnson and Mislin 2011).

Communication between the parties has been found to significantly increase trust, just as it induces higher average levels of cooperation in other social dilemma games (Sally 1995; Balliet 2010). Subjects often take this opportunity to commit to take a certain future course of action that can lead to higher gains for both parties. The interest herein lies in the possibility for the recipient to send a message to the sender saying that she promises to be trustworthy if the sender trusts her and sends her money. The question is then *why* recipients that make such promises often indeed keep their word and reciprocate trust more often when they have promised than when they have not and in a situation in which they could earn more money by not keeping their word.

Theories of Promise Keeping

The first explanation for why individuals keep promises is provided by the theory of guilt aversion, introduced in economic theory by Charness and Dufwenberg (2006), formalized by Battigalli and Dufwenberg (2007, 2009), and expanded by Miettinen (2013) and Jensen and Kozlovskaya (2016). The theory assumes that individuals derive disutility from guilt when they believe they let the other's expectations down. If an act that could bring net gains to the agent disappoints another person's expectations, it is assumed to induce unpleasant and discomforting feelings of guilt. If the agent is sufficiently guilt averse, then she might refrain from taking that action in the first place, thereby forgoing monetary gains but avoiding the experience of guilt.

The theory of guilt aversion is apt to explain human behavior in various social contexts and is especially stark in the case of promises, for a promise induces the promisee to create expectations that she will receive what she was promised. Therefore, the promisor has a reason to believe that the promisee believes that she will receive the promised performance. The promisor that breaches disappoints expectations that she personally induced in the promisee by her own

autonomous act of making the promise and is predicted to suffer disutility from guilt if she breaks the promise. The promisor must weigh this loss of utility from guilt with the monetary gain that she would achieve by breaking the promise and will keep the promise if the former is larger than the latter.

This explanation for why individuals keep promises does not rely on the moral norm of keeping promises or that *pacta sunt servanda*. Guilt-averse individuals tend to keep promises in order to avoid letting the promisee's expectations down even if they do not care about promises and contracts per se. It may be objected that promises are apt to induce expectations in the promisee, and to alter the latter's beliefs only because such a moral norm exists, and that in its absence, a promise would never be taken seriously and would never cause people to attribute payoff expectations to others. While this argument is sound, it does not invalidate the theory but rather stresses that the existence of the moral norm is a prerequisite for such feelings of guilt and payoff expectations to arise. The motivating factor driving the decision to perform is still the desire to avoid the guilt from betraying the promisee's expectations.

The second explanation for why individuals keep promises relies on individual preferences for keeping promises and for respecting shared and accepted moral norms. The moral norm (Fried 1981) or societal convention (Rawls 1971) of promising establishes that "if one says the words 'I promise to do *X*' in the appropriate circumstances, one is to do *X*, unless certain excusing conditions obtain" (Rawls 1971, 344). Promises are therefore apt to affect the behavior of promisors directly, because individuals suffer disutility from violating the moral norm, and independent of the expectations of the promisee.

An individual that wants to keep the promise in order to comply with the moral obligation that she imposed upon herself by an autonomous act of the will will do so even if she believes that the promisee does not expect to receive the promised performance. This may be so because the promisee does not trust the promisor or perhaps because the promisee does not believe that the promise was serious. The promisor that wants to comply with

the moral norm but that knows that the other does not expect performance still has a reason to perform, and not to breach and thereby violate the moral norm that promises ought to be kept.

A third explanation for why individuals keep promises relies on moral identity and on the individual's beliefs about her own values (Bénabou and Tirole 2011). Although related to the previous explanation, it differs in its content. When deciding to keep or break a promise, the individual considers what type of person each of those actions would make her (a promise breaker or a promise keeper), the desirability of those, and how much the individual values each of these identities. Keeping promises is then similar to an investment in one's own identity, for it increases the individual's confidence that she is a moral person.

Breaking promises often involves gains for the individual, and these are challenges to her beliefs, identity, and self-esteem. Challenges to a weakly held belief ("I believe it is somehow good to keep promises") elicit conformity reactions ("I will therefore keep this promise and increase my own self-esteem from being a moral person"). Effective challenges, such as very high gains from breaking the promise, threaten the individual's belief, as the person might fall into temptation, break the promise, and abandon the identity attached to that belief. When such effective challenges are directed to a strongly held belief ("I believe keeping promises is certainly the right thing to do"), then they induce counteractions that aim at reinforcing the threatened belief and at increasing the payoff of the investment in one's own identity ("I will keep this promise even in this very hard situation and therefore I will tighten my belief that keeping promises is important and, as a consequence, that I am a very moral person").

Empirical Evidence

Charness and Dufwenberg (2006) provide initial evidence for the theory of guilt aversion in an experiment that implements a modified version of the trust game in which the sender could only decide to trust the recipient or not and the recipient

could only decide to repay the sender or not. The recipient had, in their experiment, the option to send a nonbinding, free-form message to the sender before the latter's decision to trust the recipient or not. The messages sent most often included a promise (defined by the authors as any "statement of intent") and were effective in inducing trust despite being, in game-theoretical terms, mere cheap talk in the implemented single interactions. When the trustee sent a message to the trustor that did not include a promise, then only 33% of trustees reciprocated trust. In case the message included a promise, 79% of trustees reciprocated trust and hence kept the promise.

The authors, moreover, elicited the players' beliefs after they played the game, and senders were asked to guess the likelihood of trustworthiness, and recipients were asked to guess the likelihood of trust. Trustors who received a promise, in effect, delivered higher average guesses about the likelihood of trustworthiness (64%) than those who received a message that did not include a promise (50%). Trustees who sent messages including a promise also reported higher guesses about trustors' guesses (63%) than those who sent a message that did not include a promise (55%). The authors concluded that this evidence supports the theory of guilt aversion because promises induced changes in second-order beliefs, as well as in behavior, increasing rates of repayment with respect to the situation in which the message did not include a promise.

Vanberg (2008) argued that Charness and Dufwenberg's experiment did not distinguish guilt aversion from moral obligation, as the promise made by the second mover is correlated with the observed changes in promisors' second-order beliefs. Changes in beliefs may follow behavior because players may believe that others can predict their behavior and the positive correlation between behavior and second-order beliefs induced by promises might be caused by the false consensus effect (Ross 1977). Vanberg implemented a modification of the game to achieve independent variation in promises and beliefs.

In his experiment, in some cases, the promisor was switched, and the promisee faced another

different player in the position of the promisor. The promisor knew whether the promisee had received a promise from another person or not, but promisees did not know that they faced another person. Promises significantly affected behavior and beliefs toward the person to whom the promise was given (in case the promisee was not switched), increasing trustworthiness from 52% to 73%, but promises made by others (in case the promisee was switched) induced only higher beliefs, but not higher trustworthiness. When promisors faced a promisee that had received a promise from another person, they did not reciprocate trust more often than in cases where there was no promise, and independent of the fact that they had higher beliefs about promisees' beliefs, and therefore not in accord with the guilt aversion explanation.

While Vanberg's innovative design provided substantial gains in the understanding of human behavior under promises, it does not necessarily imply that the guilt aversion explanation has no empirical adherence in the context of promises. If promisors tend to keep promises in order to avoid betraying the other's expectations, and experience guilt only if they break their own promises made to the original promisee, then the guilt aversion explanation remains stark. And, in effect, there are substantial moral reasons for why promises bind only those that made the promise, autonomously and freely, and for why one experiences guilt only when betraying the expectations of the person to whom the promisor had promised and not when disappointing the expectations of persons to whom they never promised anything.

Kawagoe and Narita (2014) assumed, in accordance with this argument, that promisors feel guilt when they betray the promisee's expectation only if that expectation was raised by their very own actions, typically by their promises, but find evidence against their theory of personal guilt aversion. Ederer and Stremitzer (2016) develop a lexicographic theory of guilt aversion in which a promisee's expectations matter only if there is a direct promissory link between the promisor and the promisee, and hence only if the promisee's expectations are supported by the promisor's own promise, and provide evidence that, in turn,

corroborates this lexicographic theory of guilt aversion. The evidence in favor of those two explanations is therefore mixed, and in certain experiments, both theories can explain many but not all aspects of the data (e.g., Charness and Dufwenberg 2011).

Conclusion, Implications, and Suggestions for Further Research

There is still a lively debate on the causes of promise-keeping behavior and on the reasons that lead individuals to make good on their word. Further research is necessary not only to resolve this ongoing debate, and to provide evidence for predictions from different theories (such as self-esteem, which remains largely unaddressed), but also to study under which conditions individuals are more likely to break their promises. They might experience guilt from breach of unilateral and bilateral promises differently and might tend to fulfill the moral obligation depending on whether the promise was the result of a bargain or not.

Moreover, the relationship between those reasons for promise-keeping behavior and legal enforcement remains largely unaddressed. While there is evidence on how threats, sanctions, and legal enforcement crowd out the intrinsic motivation to perform (Bohnet et al. 2001), less is known about how those different reasons for keeping promises interact with or perhaps even determine the crowding-out effect. This might be especially relevant when parties had agreed that, in case of breach, they can recur to courts, arbitration, or other means or when they had specified a liquidated damages clause.

Wilkinson-Ryan (2010) provides evidence that individuals would require a lower amount to accept breach of a hypothetical contract that included a liquidated damages clause than in cases where this clause was absent. Moreover, they thought that breaching a contract without that clause was marginally more immoral and more likely to upset the promisee. Hoepfner and coauthors (2017) provide evidence that liquidated damages, stipulated unilaterally by the principal,

induce lower levels of effort by the agent than exogenously set expectation damages and that while the first one creates gains in removing moral considerations that hamper socially efficient breaches, it also reduces levels of cooperation.

It would be interesting to investigate whether these results are due to moral concerns or to stronger feelings of guilt and whether a liquidated damages clause creates, in the promisor's view, an option for her to breach without violating a moral norm that would apply in the absence of such clause. Alternatively, liquidated damages might induce breaches because the promisor does not experience guilt in the same manner as she would experience in the absence of such clause, as the promisor might believe that the promisee does not invariably expect to receive performance in kind but instead expects to receive performance *or* damages in cases where parties bargained and agreed on such clause.

Some scholars have started to apply the theory and findings to contract design. Charness and coauthors (2013) argue that since breaking a promise creates a self-imposed cost to the promisor, contracts should assign the responsibility for installing the promise to the party who has the residual right to breach. They report that when workers propose the contract and make a promise specifying the effort level of the worker that is due, then actual effort choices and welfare are higher than when the firm proposes the contract or the target for effort.

Stone and Stremitz (2016) apply the theory of guilt aversion to reliance investments by promisees and hypothesize that these will overinvest in reliance in order to increase the guilt that promisors would experience when breaking the promise. Legal remedies for breach decrease the need for the promisee to rely on such "psychological lock-in" in order to increase the likelihood of performance and hence tend to decrease overinvestment with respect to the situation in which there is no legal enforcement. In effect, the authors find that overinvestment is higher in the absence of damages than in their presence and that those who overinvest do so to a higher extent in the absence of remedies than in their presence.

With respect to drafting contracts, Depoorter and Tontrup (2012) report how subjects were willing to sacrifice substantial gains to prevent breach when specific performance was the available remedy and how such standard made the moral norm of keeping promises more salient to promisees, hampering efficient renegotiation. Brooks and coauthors (2012) provide evidence that framing contracts in terms of losses, including deductions in case a low output is achieved, induces higher levels of effort than contracts framed in terms of gains, including bonuses in case of high outputs. Lastly, Wilkinson-Ryan (2012) finds that the transfer of contractual rights induces behavioral changes and erodes the likelihood and quality of performance by the promisor.

The inquiry into the causes of promise-keeping behavior and the collected evidence for the predictions from different theories that are apt to explain such behavior is fascinating not only in its own terms but also in its capacity to inform contractual design and contractual enforcement. It provides insights that are relevant for drafting contracts and for enforcing them, but further investigations, both theoretical and empirical, are needed to better understand how they *should* be done to provide for the welfare of the parties and of society.

Knowledge

Brishti Guha
Centre of International Trade and Development,
School of International Studies, Jawaharlal Nehru
University, New Delhi, India

Abstract

This essay focuses on two specific aspects of knowledge that make it interesting from the viewpoint of law and economics. First, we consider the nature of knowledge as a public good, discussing how non-excludability, non-rivalry, and positive externalities in knowledge production affect private incentives and generate a demand for state intervention. We discuss the role of patent and copyright laws, as well as other forms of state support, in this context. Secondly, considering knowledge as information, we examine the economic implications of asymmetries in information, and the extent to which laws and the legal mechanism can help solve the problems created by asymmetric information.

Definitions

(i) The sum of what is known. (ii) Facts, information, and skills acquired through education or experience

Introduction

Knowledge has several properties and facets that make it interesting from a law and economics viewpoint. I concentrate on two main facets of knowledge here: knowledge as a public good

and the implications of an even or uneven *distribution* of knowledge (symmetries or asymmetries in *information*).

Knowledge as a Public Good

Once a piece of knowledge is produced, it is “non-rival” and “non-excludable.” Non-excludability means that once something becomes known, everyone has access to this piece of knowledge. This will be true unless it is possible to restrict the spread of the knowledge to a limited number of people (who pay for this privilege, something we will discuss in more detail shortly). Non-rivalry means that when one person benefits from the new piece of knowledge, this does not decrease the amount of knowledge available to others. In economic terms, the marginal cost of providing the knowledge to one more person is zero (Arrow 1962).

Non-rivalry and non-excludability together make knowledge a “public good.” From the viewpoint of social efficiency, since it costs society nothing to share an already produced piece of knowledge with one more person, one could argue that, once a new piece of knowledge comes into being, the efficient solution would be free dissemination. That is, the non-excludability property should be preserved. However, this creates a problem, because it is at odds with private incentives to *produce* this knowledge in the first place.

Knowledge production requires considerable investment of resources and time. It is essentially a risky activity which may not yield returns. Therefore, an individual will only make such investments – and come up with knowledge-enhancing innovations – if he expects a high return from doing so. However, if the knowledge he produces immediately becomes freely available to everyone, his innovation can easily be replicated. No one has an incentive to pay him for his innovation, and he in turn has no incentive to undertake an expensive and risky activity.

Unless the state steps in, therefore, the amount of knowledge produced will be far below the socially efficient level. There is another, related, reason for this. Knowledge produces “positive externalities.” That is, when people acquire

knowledge, this benefits even those who do not acquire this knowledge in the first place. This is true not just of new, startlingly innovative knowledge; it is also true of education, which typically involves imparting knowledge which has been in existence for some time. For example, when children learn about basic healthcare at school, they can share this knowledge with their (perhaps less educated) parents. Another example is the effect on crime. When fewer people are uneducated, there is less crime, so that even people who have relatively little education or knowledge benefit from a safer society. Innovative knowledge generates positive externalities of its own. New techniques learnt by workers in one firm can easily spill over into other firms if some of these workers change their jobs after mastering these techniques. Positive externalities, however, do not enter private calculations; individuals who generate the knowledge (or provide the education) know that they will not be able to capture all of the benefits of this knowledge and therefore produce less knowledge or provide less education than is desirable from the viewpoint of society.

The “free-rider” problem generated by the public good character of knowledge – the problem that anyone can freely replicate an original idea or creation – has become particularly severe in the Digital Age since the Internet makes a great deal of knowledge – articles, music, and books – available. However, it has also been an important force in earlier times. For instance, in medieval times, countries which prospered were countries that were able to make major discoveries regarding new sea routes, acquiring information about ocean currents and winds, the geography of oceans, coastlines, islands, and indeed a whole new world (Guha and Guha 2014). As such information rapidly becomes common knowledge and also because investing in acquiring such information is immensely costly and risky, the countries which made these discoveries were also the ones that received major state support in the initial phases of exploration and discovery.

These issues directly impinge on one major area of law and economics, that dealing with patent or copyright infringement. The state may try to promote incentives to come up with new pieces of knowledge by assuring individuals of

their “intellectual property rights.” This involves granting the producer of the original piece of knowledge a monopoly (for a fixed period of time before the expiry of the patent or copyright) over his creation. Prohibition of free replication and sharing thus protects the innovator’s returns, at least for a certain period of time, and enhances incentives for knowledge creation. Patents sometimes create problems of their own; a strictly enforced patent regime, for example, may also give rise to patent trolls (firms which apply for patents not because they want to develop the patented product, but to prevent other competitors from doing so). It may also induce firms to constantly sue other firms claiming patent infringement (claims which may sometimes be frivolous). This imposes some social costs in terms of the legal resources spent on such lawsuits; also, potential new knowledge producers might be discouraged lest their contribution unintentionally violate an existing patent. At the same time, given digital piracy concerns, protecting the intellectual property rights of artists (particularly musicians) is becoming increasingly challenging.

Other ways in which the state could try to resolve the problem of underproduction of knowledge by the market include direct state subsidization of research. This was what Spain and Portugal did in the medieval era (the crown funded voyages of discovery). A vast fraction of US scientific and technological knowledge (computers, lasers, aerospace, etc.) is the direct or indirect product of state-supported research, particularly defense research. Since the provision of education by the market is also below the social optimum (because of knowledge externalities and because those who impart education wish to restrict access to those who can pay), the state can also intervene in education by providing a public education system.

Knowledge as Information: Informational Asymmetries and Law and Economics

If one thinks of knowledge as information, the distribution of this information among parties engaged in an economic transaction has major implications. Consider what happens when this

information is asymmetrically distributed (*informational asymmetries*). This provides scope for the informed party to cheat the uninformed party (Akerlof 1970). For example, consider a seller and a buyer; suppose the buyer cannot tell the quality of the good he is buying on inspection. However, the seller knows the quality, either because he has produced it himself or because he has been using it for some time (in the case of secondhand sales). This generates a temptation, a *moral hazard* on the seller's part to pass off an inferior product as a high-quality product and extract a high price from the buyer while disposing of a low-quality good. This temptation is particularly strong in relatively anonymous contexts, where the seller does not have a reputation to maintain. However, the fear that this might happen might keep buyers from entering the market in the first place. Therefore, informational asymmetries can generate market collapse. In contrast, if information – or ignorance – is symmetrically distributed, moral hazard or market collapse does not arise. If buyers are informed in addition to sellers, it is obvious that they can assess the true quality of the product, accordingly leaving sellers with no opportunity to cheat them; the two can then agree on a price based on the true quality of the product. More surprisingly, there is also no problem if both buyers and sellers are *uninformed*. If the sellers are ignorant of quality themselves, they cannot systematically pass off low-quality goods as high-quality ones; buyers realize this and pay a price based on average quality, and the market does not break down.

Again, asymmetry in the distribution of information is an important issue from a law and economics perspective. Product warranties, for instance, are one solution to the abovementioned problem; they allow markets to exist by giving customers some assurance of quality. Customer protection laws also help. Ordinarily, contracts guarantee both parties in an economic transaction some rights; however, a contract can only be upheld in court if its provisions are “verifiable.” Verifiability means that a third party – lawyers or judges – should be able to check whether the contract was, indeed, violated, and it must be possible to do this without incurring a prohibitively high cost. However, asymmetry of information often

implies that contracts are *incomplete*. It is not possible to establish in court whether all their provisions were honored; this knowledge is *private information* known only to the informed party in the transaction. In this event, these contracts are not legally enforceable and become informal understandings rather than formal legal contracts. Such understandings may be enforced by means which do not rely on the legal mechanism. Some examples of such means are reputation (the ability to spread information about cheats may induce them not to alienate potential new customers by cheating existing ones), peer monitoring (in cases of group activity, see Ghatak 1999), long-term (repeated) relationships (if a customer may become a repeat customer, it may not be worthwhile to alienate him for some quick profit), competition, and the ability to signal quality convincingly (Spence 1973).

Knowledge-Specific Patents and the Additionality Constraint

Cristiano Antonelli
Dipartimento di Economia e Statistica “Cognetti de Martiis”, Università di Torino, Collegio Carlo Alberto, Torino, Italy

Definition

This entry elaborates the implications for a new knowledge policy of the full range of effects of

its limited appropriability and exhaustibility. The analysis of the appropriability trade-off identifies the dual effects of knowledge spillovers consisting not only in the reduction of incentives to the generation of knowledge but also in the reduction of R&D costs stemming from the access to the quasi-public stock of knowledge. The positive effects of knowledge spillover may compensate for the reduction of the price of innovated goods with its well-known negative effect in terms of reduced pay out of R&D activities and eventual underproduction of knowledge. The appreciation of the full spectrum of possibilities of the appropriability trade-off further refined by the analysis of the effects of the limited exhaustibility of knowledge and of the distinction between imitation and knowledge externalities enables to articulate a new framework of knowledge policy. These results, in fact, suggest the introduction of knowledge-specific patents based upon varying levels of exclusivity and call attention on the relevance of the actual additionality of public subsidies to research and development activities performed by firms.

Introduction

The recent advances of the economics of knowledge about the properties of knowledge as an economic good question the foundations of the basic framework upon which current knowledge policies are built. This entry advocates the introduction of knowledge-specific patents based upon varying levels of exclusivity and calls attention on the relevance of the actual additionality of public subsidies to research and development activities performed by firms.

The new analysis of the properties of knowledge as an economic good has shed new light on their economic effects with the identification and appreciation of the appropriability trade-off, the limited exhaustibility of knowledge, and its intrinsic heterogeneity.

The analysis of knowledge as an economic good enabled to appreciate its idiosyncratic characteristics. At first the analysis focused its limited

appropriability and, in a second stage, its limited exhaustibility. The owner of a standard economic good can fully appropriate the entire stream of benefits that stem from its use. This does not take place with knowledge because of the uncontrolled leakage: third parties can appropriate part of its economic benefits. The appropriability trade-off appreciates the dual effects of spillover where the reduction of R&D costs stemming from the access to the quasi-public stock of knowledge may compensate for the reduction of the price of innovated goods with its well-known negative effect in terms of reduced pay out of R&D activities and eventual underproduction of knowledge (Arrow 1962; Antonelli and David 2015).

The appreciation of the limited exhaustibility of knowledge is the result of a second stage of investigation of the economics of knowledge. Economics assumes that standard economic goods wear and tear. Their – repeated – use has negative consequences on their functionality. Food, once consumed, disappears and cannot be consumed again. Durable consumer and capital goods have an intrinsic limited time horizon that is further reduced by the frequency of use. The rate of usage of standard durable goods reduces their functionality. This does not take place with knowledge: knowledge can be used and used again without any negative consequence on its functionality. The limited exhaustibility of knowledge is not only physical but also economic. A standard durable economic good may become obsolete, even if it retains all its physical functionalities, because of the introduction of a superior good. The case of economic obsolescence, as distinct from a physical obsolescence, may take place with knowledge. Economic obsolescence applies to knowledge only to an extent, however. The “old” vintages of knowledge do retain an indispensable role as inputs in the recombinant generation of new knowledge. Next to its limited appropriability, knowledge is characterized, also, by a limited exhaustibility (Antonelli and Link 2015).

The identification of the limited exhaustibility of knowledge enables to qualify and specify the appropriability trade-off and to appreciate

its positive effects in terms of duration and cumulativeness that may compensate and occasionally overcompensate the negative effects of its limited appropriability (Antonelli 2017).

The identification of the new properties of knowledge as an economic good calls attention on the merits and strengths of knowledge as an economic good and its pivotal role as the engine of knowledge externalities and consequent dynamic increasing returns and questions the Arrowian assumption about the limits and weaknesses of knowledge because of its limited appropriability and the consequent market failure in terms of knowledge undersupply stemming from the lack of appropriate levels of incentives to its generation and use.

The new appreciation of the economic properties of knowledge enables also the identification of its intrinsic heterogeneity according to the varying levels of natural appropriability and exhaustibility. Knowledge should be regarded as a bundle of heterogeneous knowledge items with varying levels of exhaustibility and appropriability, rather than a homogeneous and undifferentiated stock.

This new approach that highlights the merits, as opposed to the limits, of knowledge as an economic good and its heterogeneity as opposed to its homogeneity, has strong implications in terms of knowledge policies.

Knowledge policies have been heavily influenced by the large consensus about the Arrowian knowledge market failure. The analysis of the negative economic consequences of the limits of knowledge as an economic good has been implemented for several decades and provided the base for an articulated set of economic policies aimed increasing the incentives to the generation of knowledge deemed to be insufficient.

The cornerstone of the knowledge policy that stems from the hypothesis of a generalized knowledge market failure due to the limited appropriability of knowledge is the implementation of the intellectual property rights regime designed to help reducing the negative effects of the limited appropriability and the provision of public subsidies designed to reducing the costs

of knowledge-generating activities so as to balance the negative effects of the persistent limited appropriability of proprietary knowledge even after the protection provided by homogeneous patents characterized by high levels of exclusivity.

The aim and the use of these tools have been criticized in terms of efficiency and effectiveness. As Heller and Eisenberg (1998) show, the strengthening of the intellectual property right regime that has characterized recent decades may actually deter innovation and make the case for anticommons. The current intellectual property right regime together with high transaction costs in the markets for knowledge and excess expectations of patentees regarding the value of their knowledge assets produce a fragmented knowledge landscape where owners of small complementary bits of knowledge are unable to participate in the collective effort that is needed to generate new knowledge as an output while using existing knowledge as input (David and Hall 2006). The consideration of the appropriability trade-off stemming from the dual role of knowledge spillovers as the cause of the reduction of the benefits that the “inventor” can appropriate and yet an essential facility indispensable for the recombinant generation of new knowledge (Antonelli 2007) and a cause of the knowledge externalities that help reducing the costs of new knowledge so as to compensate for the negative effects of the limited appropriability adds to the need of a new knowledge policy framework (Antonelli 2017).

The evidence shows on the other hand that automatic public subsidies and tax credits granted to R&D activities performed by private firms yield only a limited net increase of the R&D actually carried out. A large literature confirms not only that the elasticity of the actual levels of R&D activities performed by the firms that receive automatic subsidies to their R&D activities to public subsidies is well below one, but also that the additionality of public R&D subsidies – measured by the ratio of the public subsidy to the value of the additional R&D activities actually carried out – is below 100%. An important share of public subsidies

substitutes internal funds with a crowding out effect (David et al. 2000).

A New Knowledge Policy Framework

The results of the analysis carried on so far question the generalized application of the standard Arrovian framework and its strong implications in terms of knowledge policies. The limited exhaustibility of knowledge yields positive effects that may compensate and occasionally overcompensate the negative effects of its limited appropriability. The understanding of the appropriability trade-off suggests that the dissemination of knowledge helps strengthening the role of knowledge spillovers as an essential facility indispensable for the recombinant generation of new knowledge (Antonelli 2007) and the knowledge externalities that help reducing the costs of new knowledge so as to compensate for the negative effects of the limited appropriability (Antonelli 2017).

The actual increase of the amount of R&D expenditures carried out by firms matters as soon as the effects of the limited exhaustibility of knowledge in terms of the long-term accumulation of a stock of knowledge with beneficial effects on knowledge costs. This dynamics is all the more relevant when the positive effects of the limited appropriability of knowledge are considered. The knowledge externalities stemming from nonexhaustible knowledge spillovers benefit all the system. Hence, the larger are the flows of R&D activities at each point in time and the faster the accumulation of the quasi-public stock of knowledge, the larger the amount of knowledge externalities that become available.

The new evidence calls for a new knowledge policy framework able to take into account the joint effects of both the appropriability trade-off and exhaustibility of knowledge.

The provision of public subsidies to R&D activities and the intellectual property right regime should be differentiated so as to take into account the full array of outcomes of the varying levels of appropriability and exhaustibility of the bundle of heterogeneous knowledge items. Let us explore the matter in turn.

R&D Subsidies and Additionality Requirements

The rationale of the provision of public subsidies including tax credits to R&D activities carried out by firms needs to be reconsidered. The standard assumption upon which R&D subsidies and tax credits are expected to support innovation is synthesized by Fig. 1.

Automatic public subsidies and tax credits should reduce the costs of R&D activities: the supply curve of knowledge shifts from S_1 to S_2 . For a given derived demand for knowledge, the equilibrium solution changes, and on the horizontal axis, the equilibrium amount of knowledge actually generated increases from a to b . Public intervention is able to restore the equilibrium conditions that apply to standard goods and remedy the intrinsic problems of knowledge as an economic good. The system, now able to produce the right amount b of knowledge, will reach the Pareto equilibrium condition increasing the general amount of goods produced. This argument, however, rests on strong implicit assumptions about the actual shape of the derived demand for knowledge. The effects of R&D subsidies and tax credits are strongly influenced by: (i) the slope of the derived demand for knowledge and (ii) the amount of the shift. Let us consider these effects in turn.

The larger is the slope of the derived demand, the larger the output elasticity of knowledge in the technology production function. When the slope of the derived demand is large, the reduction of R&D costs engendered by public subsidies yields only a limited increase of the actual amount of

Knowledge-Specific Patents and the Additionality Constraint, Fig. 1 Expected effects of R&D subsidies

R&D activities performed by the firms that receive the subsidies.

The effects of the subsidies and tax credits on the actual levels of R&D activities depend also and primarily upon the original position of the R&D cost curve and the amount of subsidies. The downward shift from large cost levels is likely to have larger effects than additional subsidies that lower further the position of the R&D cost curve. The large empirical evidence about the limited elasticity of automatic public subsidies including tax credits to the actual levels of R&D activities and the low levels of actual additionality of public subsidies and tax credits can be interpreted as the effect of a kink in the derived demand for knowledge. For behavioral reasons, firms are reluctant to expand their R&D activities beyond a given level (Clarysse et al. 2009) (see Fig. 2).

The derived demand for knowledge before the kink is more price elastic than after it. The slope of the derived demand reflects the willingness of firms to increase their R&D activities. Before the kink, additional R&D activities and the related introduction of innovations are compatible with the current organization and strategy of firms. When the amount of R&D expenditures reaches a point, however, firms become reluctant to increase further their commitment to research activities. Additional R&D activities would imply radical changes in the organization of the firm and in its strategies. Beyond that point – the kink – the price elasticity shrinks.

The effects of public subsidies that reduce the costs of knowledge are represented by the shifts of

the supply curve from S_1 to S_2 and S_3 . Because of the kink, the subsidies that made possible the shift from S_1 to S_2 have positive effects on the equilibrium levels of knowledge generated and used in the economic system. The subsidies that made possible the shift of the supply curve of knowledge from S_2 to S_3 , instead, have negligible effects on the equilibrium levels of R&D activities. The shift brought the supply curve S_3 beyond the kink. Here crowding out effects take place. Public subsidies and tax credits have reduced the cost of knowledge but have not induced any increase in the amount of R&D activities actually performed. The amount of technological change that was deemed necessary by firms, according to the conditions of product and factor markets into which they are embedded and to whose changes they try and react by means of the introduction of innovations and hence the amount of knowledge that was required, has been already put in place. Additional funds targeted to reduce the cost of knowledge are welcomed as they do reduce the costs of the given amount of knowledge that was deemed necessary by the firm's strategy, but by no means can be used to introduce further innovations. The actual effect of the subsidies that helped to shift the knowledge supply curve from S_2 to S_3 is the use of the financial resources made available for other purposes. R&D subsidies in this case have low levels of additionality.

The lower the additionality is, the larger is the amount of the public subsidies and the larger the output elasticity of knowledge in the technology production function. The issue of the low levels of actual additionality of public subsidies to R&D becomes crucial as soon as the positive effects of R&D activities in terms of synchronic knowledge externalities are taken into account. R&D subsidies, in fact, benefit not only the recipient firm that is compensated of the negative effects of the limited appropriability of knowledge, but the whole system provided that the subsidies yield positive effects in terms of additional volumes of R&D activities and hence additional flows of spillover and consequent knowledge externalities and rates of increase of total factor productivity.

The additionality of public subsidies is easily defined by the ratio of additional R&D

Knowledge-Specific Patents and the Additionality Constraint, Fig. 2 The “true” derived demand for knowledge and the risks of crowding out

expenditures of the recipient firm i ($R\&D_i$) to the amount of public subsidies (SUB_i) received by the very same firm.

The lower is the exhaustibility, the larger the additionality should be ($\delta R\&D_i/SUB_i > 1$). The lower the exhaustibility, the larger the positive welfare effects that stem from the dynamic increasing returns associated with the increasing size of the stock of quasi-public knowledge.

Public subsidies that yield only the reduction of R&D costs and do not lead to net additional R&D activities may be justified only in a perfect Arrovian market failure when appropriability is very low and exhaustibility very high.

According to the actual levels of appropriability – and related knowledge spillover with the consequent reduction of revenue for inventors as well as increase of knowledge externalities – and exhaustibility, a range of possible additionality requirements can be considered:

- (i) Automatic R&D subsidies and tax credits with high levels of additionality requirements should be granted to knowledge items with high levels of appropriability and low levels of exhaustibility. The markets for knowledge are able to provide quasi-optimal incentives and public subsidies are mainly targeted to increase the size of the stock of quasi-public knowledge and to empower the dissemination of additional spillovers.
- (ii) Automatic R&D subsidies and tax credits with low levels of additionality requirements can be granted to knowledge items with low levels of appropriability and high levels of exhaustibility. The classical Arrovian market failure applies and R&D subsidies do compensate for the missing incentives.

Not only the types of additionality requirements but also the mix of public interventions should reflect the actual levels of appropriability and exhaustibility. Crowding out, in fact, is less likely to take place when public subsidies and tax credits target specific research programs. In this case, the State can use the provision of selective public subsidies to effectively influence the levels

and the direction of the research activities according to the public relevance of the research projects that have been submitted by firms. Targeted research subsidies and tax credits moreover help directing the research activities of a variety of firms so as to increase their compatibility and complementarity helping the dissemination of knowledge spillovers and related knowledge externalities at the system level (Antonelli and Crespi 2013).

The direct supply of knowledge by means of a public infrastructure consisting of dedicated research centers has indeed played a major role in increasing the supply of knowledge and its dissemination in the economic system especially when and if it has been coupled with dedicated and targeted public interventions especially on the demand side activating the competent demand pull mechanisms, the provision of targeted research incentives and most importantly the active role of state owned enterprises (Antonelli et al. 2014).

Table 1 summarizes the arguments elaborated so far.

The differentiation of public interventions according to the levels of knowledge appropriability and exhaustibility should concern also the structure of intellectual property right regimes.

Knowledge-Specific Patents and the Additionality Constraint, Table 1 Types of knowledge and knowledge policies

	Low exhaustibility	High exhaustibility
High appropriability	Automatic R&D subsidies and tax credits with strong additionality requirements Targeted R&D programs Direct supply of knowledge	
Low appropriability		Automatic R&D subsidies and tax credits with weak additionality requirements

Knowledge-Specific Patents: Exclusivity and Length

The analysis of knowledge properties and their effects suggests to explore the possibility to introduce knowledge-specific, rather than industry-specific, patents and to modulate not only their length (and breadth) but also their levels of exclusivity according to their actual levels of natural appropriability and exhaustibility. The case for a differentiated intellectual property rights regime based upon two types of knowledge-specific patents rests on three distinct arguments.

First, the classical argument in favor of the introduction of differentiated patents relies exclusively upon the analysis of the types of market forms of the different industries (Gilbert and Shapiro 1990). The literature that explores the optimal length and breadth of patents concentrates the analysis upon the types of competition and the market structure of industries and does not explore the differences of the knowledge items. According to this line of analysis, the length of patents should be industry-specific: the more intense is competition; the higher the productivity of R&D activity; the more intricate the reverse engineering and the shorter should be the duration of the patent (Mosel 2011). Yet it is clear that the very same knowledge may be relevant in a broad array of industries and many different types of knowledge are relevant within the same industry. The cases of general purpose technologies, such as ICT (Information and Communication Technologies) and biotechnologies, show how large can be the scope of some knowledge items that apply to a variety of well distinct industries with well-differentiated types of competition and market structure (Helpman 1998).

The analysis of general purpose technologies unveils a second major limit of the current literature of optimal breadth and length of patents: it misses the crucial distinction between imitation externalities and knowledge externalities. Imitation externalities apply when knowledge spills within the same industry and rivals can use it in their technology production function as an input at costs below equilibrium. Intraindustrial spillovers engender imitation externalities that

in turn engender the fall of the price-cost-margin of inventors with the well-known negative consequences in terms of missing incentives and knowledge undersupply. This is not the case of knowledge externalities that take place when knowledge spills across industries and is not ready-to-be-used again, but can be used only as an input in the generation of new knowledge. Knowledge externalities have no effects on the price of goods produced with knowledge in the original product market, but strong positive effects on the costs of knowledge that is used as an input for the introduction of innovations in other product markets. In this case, the outcome of the appropriability trade-off does not confirm the Arrovian postulate (Antonelli 2017).

Third, the literature has paid much attention to the possible differentiation of patents in terms of length and breadth but has paid little attention to the possibility to differentiate intellectual property rights according to their level of exclusivity. The introduction of knowledge-specific patents with both compulsory licensing and royalties enables to explore the possibility of varying levels of exclusivity as a second layer of differentiation of patents.

The design of a differentiated intellectual property right regime, based upon two types of knowledge-specific patents, should take into account the actual levels of exhaustibility and natural appropriability of the knowledge items, and of their scope of application whether intra- or interindustrial, and concern not only the length and breadth of patents but also their exclusivity. It is necessary, in fact, to pay attention not only to the negative effects of intraindustrial spillovers and imitation externalities in terms of reduced incentives but also to the positive effects of knowledge externalities and of the limited exhaustibility of knowledge. The generalized exclusivity of intellectual property rights has strong negative effects in terms of reduction of knowledge externalities that stem from the delays to the access to knowledge.

The introduction of compulsory licensing to the use of proprietary knowledge as an input in the generation of knowledge relevant in other industries different from that of inventors might

help reducing the negative effects of the standard exclusivity of the current intellectual property right regime. The definition of a fair level of royalties is clearly crucial. In this context, the identification of an optimum level of royalties paves the way to implementing an intellectual property right regime based upon the liability rule. Users have the right to access proprietary knowledge provided they pay a fair royalty. Patent holders cannot impede the use of their proprietary knowledge. The selective introduction compulsory licensing can play a major role to limit the anticommons effects of the current intellectual property right regime. In the recombinant knowledge generation process, formalized by the knowledge generation function, knowledge is both an output and an input. The impediment to use of knowledge as an input that shares the characteristics of an essential facility can block the rate of inventive activity and is in any case the cause of major costs in terms of research duplication and inventing around (Antonelli 2007).

Following Griliches (1979) and Weitzman (1996), it seems possible to assume that the inputs of the knowledge generation function are: (i) the current R&D expenditures, (ii) the internal stock of knowledge, and (iii) the external knowledge extracted from the quasi-public stock of external knowledge. The price of knowledge affects directly the revenue. The cost of knowledge as an input affects the costs. In a Cobb-Douglas specification of the knowledge generation function, standard substitution – albeit limited by substantial complementarity – between the three basic inputs implies that the changes in their cost affects total and average costs with nonlinear effects. All changes in the price of knowledge have, instead, linear effects on the revenue. It is consequently possible to identify an optimum price of knowledge and use it to implement the working of compulsory licensing-cum-royalties (Antonelli 2013).

The identification of a fair level of royalties stems from two distinct layers of analysis: (i) the analysis of the effects of the actual levels of appropriability and exhaustibility on the knowledge generation function at the firm level and (ii) the analysis of the effects of the actual levels

of appropriability and exhaustibility at the system level. Let us analyze them in turn.

At the firm level, the actual levels of appropriability and exclusivity of specific knowledge items have direct effects on the fair level of the price of knowledge and hence on the levels of royalties. The price of knowledge items characterized by low levels of natural appropriability should be larger than the price – and royalty – levels of knowledge items characterized by high levels of natural appropriability. The cost of knowledge items characterized by high levels of exhaustibility is larger than the cost of knowledge items characterized by low levels of exhaustibility: they can be used again and again with low levels of wear and tear. Hence the fair level of the royalties should be lower for knowledge items characterized by low levels of exhaustibility and larger for knowledge items characterized by high levels of exhaustibility.

Taking into account the two layers of analysis and the distinction between imitation and knowledge externalities, it seems possible to modulate exclusivity according to the levels of royalties associated to compulsory licensing. In intellectual property regimes, knowledge-specific patents are characterized by the inclusion of patents with compulsory-licensing-cum-royalties. In this case, intellectual property rights are no longer exclusive: licensing is compulsory, but not free. The levels of the royalties define the levels of *de facto* exclusivity. High-level royalties imply strong *de facto* exclusivity. Low-level royalties imply weak *de facto* exclusivity.

Intellectual property right regimes characterized by high exclusivity should not be granted to knowledge items characterized by low levels of exhaustibility for two strong reasons: (i) low exhaustibility compensates already the negative effects of low appropriability, (ii) exclusive property rights for knowledge items with low levels of exhaustibility have large opportunity costs at the system level as they limit and delay the knowledge spillovers and hence the access to knowledge externalities and the recombinant generation of new knowledge (Antonelli 2017).

The design of differentiated intellectual property rights in terms of both terms and exclusivity

Knowledge-Specific Patents and the Additionality Constraint, Table 2 Types of knowledge and externalities and types of knowledge-specific patents

	Low exhaustibility	High exhaustibility
High appropriability	Short-term patents with weak exclusivity especially for interindustrial uses	
Low appropriability		Long-term patents with strong exclusivity especially for intraindustrial uses

levels should be implemented according to the intrinsic heterogeneity of knowledge in terms of both natural appropriability and exhaustibility with the introduction of knowledge-specific patents:

- (i) Short-term patents with weak exclusivity should be granted to knowledge items characterized by low exhaustibility and high natural appropriability and apply to interindustrial users.
- (ii) Long-term patents with strong exclusivity can be confirmed only to knowledge items with high levels of exhaustibility and very low levels of natural appropriability and apply to intraindustrial users (Table 2).

Conclusions

The new understanding of the appropriability trade-off and of the limited exhaustibility of knowledge questions the basic frame of current knowledge policy. The appreciation of the positive effects of the limited appropriability of knowledge in terms of reduced knowledge costs and of the limited exhaustibility of knowledge on its intertemporal derived demand and on the long-term duration of the positive effects of the spill-over contrasts the foundations of the Arrovian postulate. The current frame of knowledge policy builds up the Arrovian postulate according to

which the limited appropriability of knowledge is itself a cause of market failure consisting in the undersupply of knowledge because of the lack of appropriate incentives to generate it. Consistently, the current frame of the knowledge policy aims at increasing the incentives to the generation of knowledge so as to remedy the negative effects of its intrinsic limits. The appreciation of the appropriability trade-off and of the limited exhaustibility of knowledge, instead, calls attention on the opportunities for growth that stem from the properties of knowledge in terms of dynamic increasing returns rather than on its limits as a cause of market failure.

The appreciation of the new properties of knowledge and the distinction between imitation and knowledge externalities provide basic support to an alternative knowledge policy framework that should be aimed at strengthening the opportunities for growth that stem from the increase of the amount of knowledge available in a system at each point in time as a source of knowledge externalities.

Public subsidies to R&D activities performed by firms should be finalized to increase the actual amount of knowledge generated in the system, rather than to compensate firms for the missing revenue caused by the limited appropriability of knowledge by lowering knowledge costs. The actual additionality of public subsidies to R&D activities should become the basic constraint and the basic target. Public subsidies should be granted to firms that are actually able to use the subsidies not only to reduce their R&D costs but also to increase the amount of knowledge generated.

Intellectual property rights characterized by intrinsic exclusivity have been justified and implemented to remedy and increase the low levels of natural appropriability of knowledge. The exclusivity of patents has major negative consequences in terms of reduced dissemination of knowledge that limits the access and use of proprietary knowledge as an input into the recombinant generation of new knowledge. Exclusive intellectual property rights do increase appropriability and hence the incentives to generate knowledge but are the cause of major

opportunity costs in terms of missing opportunities to reduce the actual costs of new knowledge. Their use should be limited to intraindustrial uses.

The design of intellectual property rights with limited exclusivity based upon compulsory licensing cum fair royalties seems better able to combine the necessary support to knowledge appropriation and hence to the incentives to its generation together with a reduction of the severe limits caused by exclusivity to the dissemination of knowledge and hence to the levels of knowledge externalities that are crucial to support growth. Such patents should apply to all uses of knowledge outside the industry of inventors.

Finally, it seems necessary a radical departure from the standard assumption of the homogeneity of knowledge that underlies the current frame of knowledge policy. It is by now necessary to regard knowledge as a bundle of highly differentiated items. Knowledge items differ substantially in terms of levels of natural appropriability and exhaustibility. Knowledge policies should be differentiated accordingly so as to modulate both subsidies and the design of intellectual property rights according to their levels of natural appropriability, exhaustibility, and scope of usage.

Knowledge-specific patents as well as differentiated public subsidies with varying levels of additionality requirements should be designed and implemented to take into account the actual properties of the knowledge item under consideration.

Labeling

John M. Crespi
Iowa State University, Ames, IA, USA

Synonyms

[Certification Labeling](#); [Marking](#)

Definition

Labeling is the affixing of a mark and symbol or identifying word or phrase to a product or process for the purpose of providing information about an undetectable attribute. The attribute could be a product ingredient, a manufacturing process, or an aspect of the production process anywhere along the supply chain.

Labeling

The economic study of *labeling* generally refers to the research regarding the welfare impacts of descriptions, marks, or symbols affixed to a product for the purpose of providing consumer information, typically concerning a credence attribute. A credence attribute (Darby and Karni 1973) exists when consumers cannot detect the attribute even after consuming the product and must rely

upon provided labeling information. Examples of labeled attributes are nutritional labels, organic labels, eco-labels, or safety information. Such attribute labels concern either the final-stage manufacturing of the product or some aspect of the production process itself. Further examples include wine appellations, production methods such as “sustainably grown” or “bird friendly,” the inclusion or exclusion of genetically modified ingredients, “fair trade,” “country of origin,” or even more well-known labels such as single malt or Champagne, which refer to processes or regions that imbue the product with a demand-shifting attribute. Along with being credible, labels, to be successful, must overcome coordination and free-riding problems, and as such, many fall under governmental regulations. In the United States, marketing orders and checkoff programs allow growers to jointly market a product using a producer association label (e.g., “Certified Angus Beef”), while other nations use similar regional and product appellations. Some labels are quite broad, encompassing large classes of products such as France’s “Label Rouge” program to indicate quality. Labels may be for attributes desirable by all consumers as in the case of food safety or nutrition (e.g., vertical differentiation) or desirable to some consumers, while other consumers show relative indifference as in the case of organics and genetically modified ingredients (e.g., horizontal differentiation). The label can be either positive, indicating the presence of the

attribute, or negative, indicating the attribute's absence. Most economic research on labeling has examined descriptions on food products.

In its broadest sense, a label could encompass branding and other private-party signaling although more often research on labeling focuses on governmental or producer association labels not directly affiliated with any one manufacturer where truth in labeling statutes might be difficult to apply (Giannakas 2002). For example, while consumers might trust a winery's claim that the grapes used are 100% cabernet, the consumer may be less inclined to trust the winery on whether its workers were paid a fair wage or whether the grapes were organically produced. Conversely, such a winery may wish to build a reputation for incorporating such attributes in its manufacturing, and seeking out a third-party certifier could be a smart business decision.

The economic research often takes as a datum that consumers would not trust the manufacturer to correctly self-report a credence attribute. There are practical reasons for this. It may be impossible to detect through chemical testing, for example, whether a firm's ingredients are organic, and it would be arduous for consumers to detect whether a firm's suppliers follow environmental safeguards. Certification agents (public or private) who specialize in such detection are seen as necessary in cases where the labels signal the production methods, regional sourcing, environmental impacts, and safety or quality of a good. The absence of the label for a desirable attribute creates a so-called lemon problem (Akerlof 1970) where consumers who have a higher willingness to pay for a good with some attribute (e.g., free of antibiotics or genetically modified ingredients) or produced using a preferred production method (e.g., kosher or dolphin safe) have no way of discerning the quality in the absence of the label. If other firms could make the claim without adhering to the labels' standards, consumers would learn to distrust any labeled good resulting in a crowding out of the desired attribute despite the presence of consumers who would purchase it.

Numerous studies have examined consumers' willingness to pay for or avoid paying for particular credence attributes (see Caswell and Mojduszka 1996 and the extensive discussions

of studies in Krarup and Russell 2005). Research on the upstream environmental benefits of labeling consumer products is also an area of much research (Krarup and Russell 2005). Along with the welfare implications in general, research on policy effectiveness have incorporated models of product differentiation and market structure to examine the impacts of labeling on vertical coordination, market power, and international trade (Bonroy and Constantatos 2015; Lapan and Moschini 2007; Roe and Sheldon 2007), reducing costly searches (Teisl and Roe 1998), and whether eco-labeling in particular might be counterproductive to environmentalists' desires (Matoo and Singh 1994). Research also delves into label proliferation, which arises when products contain multiple, sometimes competing labeled, attributes (Kiesel and Villas-Boas 2013; Marette 2014); behavioral economics through framing (how the wording of a label impacts welfare; Levin and Gaeth 1988; Crespi and Marette. 2003a, b); comparing label policies with other policies (Bonroy and Constantatos 2015; Marette and Roosen 2011); voluntary versus mandatory labeling (Roe et al. 2014); and the impact of labels on brain functions (Bruce et al. 2014).

Laffer Curve

► Laffer Effect

Laffer Effect

Francesco Forte
Department of Economics and Law, Sapienza - University of Rome, Rome, Italy

Abstract

The Laffer effect, that takes its name from Arthur Laffer, the economist who presented

it in discussions to support tax cuts by US President Ford (1974–1977), consists of the increase of the tax revenue caused by reductions of tax burdens. This principle had already presented in the past by Suetonius (119/122), Pufendorf (1672), Hume (1742), Montesquieu (1748), in various contexts, either for the maximization of tax revenues or for that of national wealth and welfare. In contemporary economics, the tax cuts to increase tax revenue and GDP have been theorized in a supply side and public choice approach by James Buchanan and others, either as mere tax policies or in broader supply side-policy frame, as that of deregulation. The Laffer effect may be misunderstood through fiscal illusions. It has often been muddled with Keynesian demand-side approaches.

Definition

Effect of tax rate reduction which does not reduce the tax revenue but may even increase it.

Synonyms

Laffer curve

Laffer curve takes its name from Arthur Laffer. Wanniski (1978) writes that this economist and professor of Business Economics at the University of Southern California – and adviser of the president of the USA Gerard Ford in 1974–1977 – presented it in a discussion, to support a tax cut, drawing the curve of Fig. 1 and telling that “There are always two tax rates that yield the same revenues.”

The tax rate is on the vertical axis, while the revenues are on the horizontal axis. The revenue depends from the size of the taxable basis (which does not appear in the graph) and from the level of the rate. The tax rate affects the revenues through its relation with the public expenditure and through its effect on the behavior of the taxpayers. Initially an increased revenue devoted to public expenditure gives benefits greater than the cost of

Laffer Effect, Fig. 1 The Laffer curve

the taxes in terms of loss of wealth and incentives. Therefore, the revenue increases both because the rate increases and because the taxable basis increases. Subsequently the benefits of the cost of the tax for the taxpayers overcome the benefits of public expenditure, and the negative effects of the tax increase reduce the taxable basis at an increasingly rate. Therefore, the revenue increases at a reduced rate because the reduction of the taxable basis reduces the revenue effect of the increase of the tax rate. After a point, the taxable basis diminishes in a proportion greater than the increase due to the rate increase and the revenue diminishes. Thus, any amounts of revenue except the point of maximum revenue may be achieved with two alternative tax rates as those indicated with $A = B$ and, respectively, $C = D$. Wanniski, however, appears to give a *wrong supply-side* explanation of the Laffer curve because for him the maximum rate seems the best not only from the point of view of revenue maximization but also from the point of view of production maximization. This is not true because the maximum revenue does not imply a maximization of the economic activity taxed as shown clearly by Monissen (1985, 1999). The situation, indeed, is similar to that of a monopolist, as pointed out by Brennan and Buchanan (1980), dealing with a “Leviathan state.” Wanniski, as Laffer’s predecessor, quotes Montesquieu and Hume. But while in Montesquieu the principle of the optimal tax rate

seems to be in relation to the maximization of the budget revenue (Montesquieu (1748), Book 13, Chapter VII, writes that the free government maximizes its revenue when the revenues of taxpayers are maximized and, in Chapter XV quoted by Wanniski, adds that the free government that increases too much its taxes shall lose the power in favor of a despotic state with lower taxes.), in Hume (According to Hume (1742), VIII § 8, increases of taxes may induce taxpayers to increase their efforts, but, after a point, the opposite taxes place.), it appears to be in relation to the maximization of the production taxed, which may imply the maximization of the national wealth (The same is true for Adam Smith (1776) fourth maxim of taxation, as for taxes that obstruct the industry of the people or discourage them.). With this ambiguity, the Lafferian principle goes back to Suetonius (Suetonius (119/122), Chapter III, The life of Tiberius, § 32) – who refers that the emperor Tiberius “to governors who recommended burdensome taxes for his provinces, wrote in answer that it was the part of a good shepherd to clear his flock, not skin it.”

Thus, the Laffer curve presents two ambiguities: it may be conceived for a partial equilibrium, with GDP as given, or for a general equilibrium. While in the short run the GDP may be given, in the longer term it may change, through the effect of taxation and of exogenous factors, and this may imply that the tax revenue Laffer effect differs from the tax revenue/GDP effect. Therefore, many fiscal illusions may arise (Fedeli and Forte 2014a, b). Pufendorf (1672, Book VIII, Ch. I §5) mentioned by Gerloff (1948) (see Gerloff (1948) pp. 2010–2014 on the Gesteiz der Verringerung der Steuerfälle in Blankart (1991)) presents a partial equilibrium case of the revenue of an excise tax in a scenario of international or interregional tax competition, where a government may get a gain of revenue, by reducing its tax to the level of that of competing governments.

In Forte, Bondonio, and Jona (1980), p. 48, I presented the (partial equilibrium) curve of Fig. 2 similar to that of Laffer, with inverted axes, where the tax rate and the taxable basis are considered *under a given GDP*. The taxable basis is negatively influenced by the tax

avoidance – done by evasion, elusion, and outflow of the taxable matter – caused by rate increases. A reduction of the rate may increase the tax revenue, at any level of GDP, but then also GDP may change and the elasticity of the taxable basis to GDP may change.

A similar Lafferian curve is given by Gutman (1981) and by Frey and Weck (1983) as presented in Blankart (1991) Chapter 11, § 5), considering the effects of the level of the tax rate on shadow economy. In these cases the tax revenue/GDP ratio in the subsequent years is influenced both by the effect of tax burden on the shadow economy and by the way in which it is assessed in GDP. Buchanan and Lee (1982a, b) argue that reduction of taxes with balanced budget, in

medium term, may give increased GDP and additional revenues, thus allowing an increased public spending, with a balanced budget and a smaller government size as in Fig. 3 presented in Frey and Weck (1985), p. 103, which is valid also for the tax revenues/GDP ratio.

Later on J. Buchanan connected these Laffer effects to increasing returns and work ethics (Forte 2008).

A dangerous ambiguity of the Laffer curve, in the short and longer term, derives from its extension to the Keynesian tax reduction from a demand-side point of view, approved by Laffer (2004) (The ambiguity of Laffer’s own view is increased by the fact that he considered Kennedy’s tax cut, inspired by the Keynesian doctrine, as an application of his principle. Canto, Joines, and Laffer (1982), however, put the Laffer curve only in a supply-side context.), quoting Keynes (1933) who argues that a reduction of taxes *in deficit* may increase the national income by increasing the demand, thus bringing back a balanced budget at a higher level of income (Keynes (1933), p. 338, “taxation may be so high as to defeat its object, and that, given sufficient time to gather the fruits, a reduction of taxation will run a better chance than an increase of balancing the budget”). The deficit-tax cut theorized by Keynes and many neo-Keynesians introduces a fiscal policy “Trojan horse” that may lead

Laffer Effect, Fig. 2 Forte (1982)’s Laffer curve

Laffer Effect, Fig. 3 The long- and the short-run Laffer curves

to a “democracy in deficit” Buchanan and Wagner (1977). Hypothetical future Laffer effects may be invoked to justify a popular budget unbalance and redistributions of taxation from consumptions to savings and from poor to rich. But while in a Keynesian world this can increase GDP by increasing consumption, the opposite may happen untrue in a supply-side approach.

Tax illusions are very relevant as for the Laffer effect. Forte (1987) shows that a fiscal bureaucracy pursuing the gross revenue maximization may not maximize the net revenue because the marginal costs of collection may exceed the marginal increase of revenue.

Laffer effects are also conditioned by the institutional scenario. Tax cuts joint with a reduction of regulations have caused Laffer effects as shown by Fedeli and Forte (2008) and Fedeli, Forte, and Zangari (2008) for reductions of social security contribution accompanied by deregulation of the labor market. Trabandt and Uhlig (2009), within a neoclassical model of growth, assessed how much the USA and EU may still increase taxes without a negative Laffer effect. Fedeli and Forte (2014a) demonstrate by empirical research on OECD countries that high deficits and high taxes may reduce GDP with implications for long-run Laffer effect. Tanzi (2014) defines the Laffer curve as a muddle. Nevertheless, in this muddle, one carefully looking may find gold nuggets.

Neurolinguistics Laboratory, Department of
Translation Studies, Faculty of Languages,
University of Gdansk, Gdansk, Poland

Abstract

The aim of this contribution is to discuss the characteristic features of economic discourse. Moreover, the language of economics is studied through the prism of domains, approaches, and perspectives used to investigate the complexity of economic communication. In addition, different methods of researching the language of economics are presented and discussed, including interdisciplinary methodologies.

Introduction

Modern economics, as other domains in life, can be characterized by different features of the twenty-first century. One of the key factors shaping modern economic reality is globalization, represented in, among other things, relatively easier access to different resources, of material and nonmaterial character, that have been previously limited because of, among other things, geographical or technological barriers. The power of technology (in terms of transport and communication possibilities), represented in its influence on the global market, has led to the growing importance

of linguistic skills, indispensable to meet the needs of stakeholders coming from different parts of the world. Since the modern economic emporium has shrunk as far as geographical or technological distance is concerned, companies may operate simultaneously in various countries by communicating via telephone, emails, or social networking tools with the representatives of markets that could not have been reached in the past. Communication itself also varies in comparison with the type of interactions popular in the past century. In the area of Tofflerian prosumers, customers are not only passive receivers of goods and services but they are also active creators of merchandise and organizational culture. They do not only design products themselves but they also construct the dialogic sphere in which they participate as proper members, together with producers, users, and the nonhuman entities, such as goods and the broadly understood technological environment of economic reality. The interactional approach is also highlighted by Klammer (2007, p. 15), who states that *economics is a conversation, or better, a bunch of conversations, and economists are economists because they are in conversation with other economists*. The development of economic discourse takes place in various domains, leading to the appearance of new subdomains and methodological coexistence with other academic disciplines. The burgeoning research encompassing the representatives of different disciplines makes the language of economics a complex and multidimensional phenomenon. As far as scientific studies are concerned, the article by William Warrand Carlile (1909) was one of the first works on the language of economics. Nowadays, the role of economic communication is studied by both researchers and businesspeople in order to make this type of language for special purposes even closer to speakers representing different levels of economic knowledge. At the individual level, the popularity of the language of economics is also connected with the growing role of goods in the life of individuals and the importance of material possession for some people. Taking the organizational dimension into account, effective communication exercised both internally and externally is one of

the key determinants of company effective performance on competitive markets.

The Language of Economics: A Definition

The language of economics can be understood in at least two ways. The first method is to treat language in the broad sense, analyzing both verbal and nonverbal (e.g., pictorial or olfactory) communication. The language of economics investigated in this way can be observed from a more holistic perspective, drawing one's attention not only to the linguistic layer of economic discourse but also to other senses that shape the rhetoric of economics. Taking marketing as an example, verbal communication stimulates purchasing behaviors of customers, together with other types of experience that determine the way reactions and behaviors are shaped. For example, smells and sounds used in shops may intensify the perception of words aimed at making buyers interested in products. Thus, the approach to language is synesthetic, showing how verbal, pictorial, olfactory, and audio dimensions create the way a given phenomenon is encoded and decoded. Another perspective is to concentrate exclusively on the linguistic level of economic communication, focusing only on words and their role in this type of language for special purposes.

The next field of analysis is the dichotomy of inner and outer dimensions of economic discourse. At the internal (mainly organizational) level, the language of economics plays the following functions. First, it facilitates internal communication between specialists representing different areas of economics, offering them the common ground for specialized interactions. Secondly, organizational discourse offers the possibility of "closed and exclusive communication," relying on selected terms understood only by the members of a given organizational community. This results in a creation of a corporate code and, consequently, a strengthening of organizational identity. Analyzing the language of economics from a more external perspective, it stimulates effective communication between economists

and laymen, often coming from different linguistic and professional backgrounds. For example, the dominance of English terms in economic discourse makes it easier for specialists speaking different languages to communicate by relying on international concepts understood by different users, regardless of their mother tongues.

The Language of Economics: General Characteristics

The language of economics does not exist in a vacuum; it shapes and, at the same time, is shaped by other domains of life, such as politics, culture, geography, technology, and economics. The multidimensionality characterizing the language of economics can also be observed at the level of stakeholders. The participants in economic dialogue can be categorized by taking into account their level of knowledge on economic matters and their professional involvement in organizational matters (employees vs. nonemployees). The language of economics should also take into account users with special needs, visible in, e.g., adjusting product information for the blind. Thus, the studies on economics discourse should also encompass communication types and tools tailored to the needs and expectations of a diversified audience. Apart from the mentioned external determinants, the language of economics is a complex phenomenon within itself. One of its key characteristics is the high number of borrowings and loans in its lexicon. In many languages of economics, loanwords constitute a large part of economic dictionaries. Taking the example of English, many economic concepts come originally from French, making it the most powerful language donor, contributing about 40–60% of all terms, depending on subdomains, such as law, accounting, or general business. An example can be coupon used in finance, entrepreneur used in management, or force majeure used in business law. Another key donor language is Latin, with terms such as *moneta*, *pondus*, and *centus* representing the monetary dimension of economics. Another important foreign language that influenced the current state of English economic lexicon is Japanese. One of

the areas rich in Japanese terms is management philosophy, with such terms as *genba shugi*, *keiretsu*, and *zaibatsu*. Another field that relies on Japanese words is technical analysis, with such names describing candles as *Harami*, *Marubozu*, or *Doji*. The next linguistic donor is Greek, with such terms as kappa, rho, or phi used to describe options. Other foreign concepts in the English language of economics come from Italian (e.g., *agio* and *mezzanine*), Spanish (e.g., *cargo* and *gambit*), as well as the North Germanic languages and German (e.g., *blitzkrieg* *tender offer*) as discussed by Bielenia-Grajewska (2009a). The linguistic dimension of economic discourse is also connected with literal and figurative economic communication. *Literal economic communication* can be investigated through the way certain linguistic tools are selected and used, such as verbs, nouns, and adjectives, and the way their direct meaning influences communication. *Figurative economic communication* encompasses such notions as metaphor, metonymy, idiom, personification, and simile. Since not only verbal communication constitutes the language of economics, rituals, rites of passage, and the arrangement of furniture or office space constitute the identity of modern companies. Focusing on the verbal dimension of economic discourse, McCloskey (1995, p. 218) states that *economists are poets but they do not know about it*. When one observes the language of economics, it is noticed that there are many metaphors used to denote economic reality. They serve different functions. On the individual level, they are used by economists to construct their own idiolect that can be viewed as an important element of their identity. In addition, metaphors make economists or businessmen outstanding and remembered by others. The same can be observed in the case of economic journalists, who rely on figurative metaphors to make their content more interesting and intriguing. This feature is important in the case of covers and headlines that are to attract potential readers to the articles themselves. On the social level, they stimulate effective communication between people of different knowledge levels on economic topics. A metaphor, relying on a well-known domain, is more easily perceived and understood

than a complicated economic term. The application of metaphors to describe economic environments can be observed at different levels of economic discourse. Taking the microsphere into account, metaphors are used to denote products or strategies. The examples include such terms as *porcupine defense* or *black knight*, used to describe the world of mergers and acquisitions (Bielenia-Grajewska 2009b). The meso level encompasses organizations; in that case, metaphors are used to create the image of a company in the eyes of stakeholders. The following examples come from the food industry: organization as a teacher, organization as a network, organization as a protector, organization as a traditionalist, organization as a travel guide, and organization as a family (Bielenia-Grajewska 2014). Company linguistic identity can be studied through the prism of the 3Ps model of company linguistic identity and its metaphorical dimension. The application of three angles, such as personnel, purchasers, and products, stresses how metaphors determine corporate communication and how they shape the selection of products by attracting stakeholders to companies and their offers (Bielenia-Grajewska 2015). The examples to support the discussed phenomenon can come from different domains. One of them is the animal world; animals, having distinctive features and being widely known, constitute an important metaphorical donor. Another one is weather, being a varied phenomenon, offering both positive and negative notions. In addition, the unpredictability of weather conditions is used to denote economic phenomena that cannot be foreseen and controlled. Another domain is literature, with metaphorical names originating from tragedies (e.g., *Lady Macbeth Strategy*) or myths (*Sisyphean struggle*). The next domain is medicine, with such metaphors as *pills* or *heal* used to describe how economic conditions can be improved.

The Language of Economics: Approach Perspectives

Another way to study the growing interest in the language of economics is to investigate it through

the prism of approaches and theories determining modern reality. Different assumptions originating from social studies and the humanities can be used to research the language of economics as a scientific phenomenon since they often stress the changeability and complexity of economic discourse.

The Language of Economics as a Re-enchanted and Fluid Reality

The interest in the language of economics can be viewed from the perspective of re-enchanted reality. As Reed (2002, p. 35) discusses, *re-enchantment refers to a symbolic or discursive, rather than material or structural, reworking of the ways in which organizations discipline and control their members. It shifts the focus of attention away from material technologies and organizational structures to the cultural and linguistic forms through which members represent and communicate their organizational identities*. Thus, modern business can be studied as an example of re-enchanted entities, with language showing how people create the economic reality, exercise power, and become competitive. An example is the symbolic layer of economic communication, with metaphors, fairytales, and myths used to denote organizational culture.

Applying a broader theory, such as postmodernism, allows researchers to study the language of economics as a dynamic phenomenon that escapes easy categorization. For example, the Baumanian concept of liquid modernity offers the opportunity to investigate language without posing any rigid boundaries between language, economics, politics, and private life, but by treating language as an element of fluid reality that can merge with other entities and influence them.

The Language of Economics as a Systemic Entity

A similar perspective is connected with looking at the language of economics as an open system. In this approach, attention is drawn to the language of economics as an element of a more complex system and, at the same time, to economic communication as an entity constituted of smaller

elements. This line of investigation stresses the multilayered and interdependent character of economic discourse. The mentioned systemic perspective exemplifies different subsystems within the language of economics itself (such as the language of accounting, the language of banking, and the language of management) as well as highlighting that the language of economics is an element of a more compound phenomenon, such as the domain of languages for special purposes. At the text level, the traces of systemic approaches are visible in the notion of a paratext by Gerard Genette (1997). Paratextual materials accompany the main text in different ways. In the case of economic books, such notions as reviews, cover layout, or interviews with authors can be examples of paratexts. Another textual approach is intertextuality as discussed by Julia Kristeva (1980), stressing the role of other texts or their elements in creating subsequent works. The systemic character of economic communication is also represented by network approaches. For example, Actor-Network Theory (ANT) stresses that both living and nonliving elements shape the performance of a given entity. Taking the language of economics into consideration, not only human beings determine the way language is created and used. For example, technological tools, such as the Internet and telephone, and standard modes of information creation and distribution, including books or magazines, shape and maintain economic discourse. Another network theory is social network analysis (SNA) that offers discussion on grids, lattices, and relations between those creating and using organizational networks. The next concept that stresses the interrelation of linguistic phenomena is heteroglossia. This term, originating from the Greek words hetero (different) and glossa (language), was introduced by the Russian linguist Mikhail Bakhtin (1986) to discuss, e.g., different parts of speech in literary works. Nowadays the term heteroglossia is implied to stress the plurality and complexity of modern communication, visible in the concept called *heteroglossic linguistic identity of modern companies* (Bielenia-Grąjewska 2013). Applying this notion to the discussion on the language of economics facilitates the study on the

multivocality of economic discourse, observed at micro, meso, and macro levels. The micro perspective is dominated by hybridity at a word level, represented in terms originating from different domains of life. The meso level, on the other hand, can be viewed through the prism of textual representation, studying different types of texts used in economic discourse. The macro approach, on the other hand, is connected with different voices shaping the language of economics, represented in the way different experts and laymen communicate. The application of hybrid approaches to the studies on the language of economics can be observed in the concept of *hybrid linguistic identity* (Bielenia-Grajewska 2010); the exposure to different linguistic codes leads to the creation of a new linguistic representation that possesses unique features. It is not only the fusion of different languages or dialects but it also results in an exclusive communication style, being a novel linguistic strategy that offers new possibilities of usage and research. The hybridism of economic communication is represented at different levels, starting from the word level and finishing with the language of economics as a complex phenomenon.

The Language of Economics: Technological Perspectives

The language of economics is a dynamic phenomenon. The mentioned dynamism has different reasons, with technology being an important determinant shaping economic discourse. Technological determinism is visible not only in the way the language of economics is created but also in the way it is stored and offered. As far as the creation of economic discourse is concerned, technological advancements have resulted in a language of economics that is efficient and economical. Technology has also created new places where the language of economics can be stored. In addition, new economic terms and expressions are coined and used to denote novel technological and economic reality. The language of economics can also be studied from the perspective of written and spoken forms of interaction. As far as the written types are concerned, they involve both standard and novel modes of communication, such as

letters, emails, offers, websites, social media communication tools, and leaflets. The mentioned channels of economic communication can also be subcategorized through the perspective of synchronicity and possibilities of alternation. For example, websites can be updated very quickly, whereas new catalogues and leaflets have to be prepared, printed, and distributed. The spoken side of economic discourse encompasses business talks, negotiations, speeches, as well as telephone or online conversations. Both written and spoken channels of economic communication undergo technological changes. The growing popularity of online communication tools, such as electronic billboards, social media, and communicators, has enriched the spectrum of communication possibilities.

The Language of Economics: Discipline Perspectives

The Language of Economics: Linguistic Perspectives

In scientific literature on economic discourse, one can also come across such terms as *economese* or *econospeak* and *dialogical economics*. Although they vary as far as the field of interest is concerned, they draw attention to the linguistic side of economics. Linguistic perspectives focus, as their name suggests, on the language-related aspects of economic communication. Detailed characteristics of this approach are presented in the section devoted to the main features of economic discourse.

The Language of Economics: Educational Perspectives

The discussion on the language of economics from educational perspectives is connected with investigating how the language of economics can be taught and learnt. It focuses on the studies devoted to languages for special/specific purposes and their relation to general language. Using English as an example, the language of economics is often researched and taught as English for Business. This line of teaching provides a type of instruction that meets the needs of economists.

Apart from the general focus on the language of business as such, teachers also offer more tailored courses, such as English for Marketing, English for Accounting, and English for Management, to meet the expectations of accountants, marketers, and managers. Educational perspectives also encompass necessary books and other sources to study the language of economics. Thus, the educational dimension also includes printed and online dictionaries, coursebooks, CDs, and supplementary materials.

The Language of Economics: Economic Perspectives

The relations between language and economics can be studied by investigating how certain linguistic policies and behaviors increase or decrease economic performance. One aspect is the connection between knowledge flows and economic efficiency. For example, providing proper translation increases the chances of companies to be successful on foreign markets. Apart from translation, the notion of localization becomes more and more popular since online content does not only have to be translated but also localized, taking into account the needs and expectations of the target market. For example, George Akerlof (1970) discusses the notion of *adverse selection*. This concept denotes situations when the asymmetry of information leads to less favorable positions of products or services on the market and lower selection rates among customers, in comparison with products that benefit from efficient informational coverage. Another notion that can be studied is trust. It is also language dependent since effective communication between interlocutors determines their cooperation. The economic perspective of language can be exemplified at different levels. One of them is the supranational perspective, examining the role of a lingua franca in creating global economy. The national perspective may concern the place of a given language in creating a national economy and its role in international business. The national perspective may also concern how national linguistic policies determine the usage of national language in organizational settings. This dimension encompasses the attitude to national languages used in

international companies and the place of minority languages and dialects within national economies. An individual perspective can also be analyzed by looking at the predicted possible gains related to learning a given foreign language.

Apart from the language of economics, there are other concepts that sound similar but carry a slightly different meaning. One of them is the *economics of language* that focuses on how language determines the economic side of individual or organizational performance, showing, e.g., the relation between language and employment income, the economic dimension of second-language acquisition, language and immigration, or language and rational choice theory (e.g., Grin 1994). The topics include the following spheres of investigation: the economics of the multilingual workplace (Grin et al. 2010) or the relation between languages and economic advantage (Ginsburgh and Weber 2011).

The Language of Economics: Political, Social, and Historical Perspectives

The link between politics and economic discourse is visible in the creation of terms related to a given economic system in a country. Politics is represented in different regulations on national languages as well as the political system and its influence on the economy. Language also offers information on socioeconomic conditions. There are studies in literature stating how one's selection of semantic and syntactical choices is connected with one's upbringing, education, and profession. In the language of economics, the selection of words may mirror one's knowledge of a given economic domain. The historical perspective can be studied by looking at how loanwords entered the economic lexicon of a given language or how foreign syntax was adopted in economic communication.

The Language of Economics: Biological Perspectives

The dynamic perspective of economic communication can also be discussed from the perspective of memetics. Originating from genetics and studied by such scholars as Richard Dawkins or Susan Blackmore, memetics focuses on replication in

culture; it can be used to discuss how new economic terms “replicate” in a new economic reality. For example, new economic terms that appeared in Poland accompanying the change of the system in the 1990s first spread among economists and journalists and later became known also among laymen. A concept called *viral meme* that transmits because of its emotional connotations is also applicable to economic memes. Such economic phenomena as market crashes, mergers and acquisitions, or failures of financial institutions, together with terms denoting them, can be treated through the perspective of viral memes. Examples constitute metaphorical names describing M&A, such as *white knight* or *black knight*, with the “color of armor” showing the intentions of acquiring companies. Moreover, the success or failure of “infecting” the public with a new term depends on how the translation of a given term is accepted by the target audience. For example, some economists prefer the English term *futures* instead of long and descriptive versions in their mother tongues. The analogy to genes is also visible in the case of viral economic terms that gain popularity very quickly (Bielenia-Grajewska 2008). The memetic approach to economics can be noticed in the contribution by Měřo (2009), and the concept of *Mom* that can be defined as the piece of information that describes a company and together with other *Moms* creates economic entities.

The Language of Economics: Neuroscientific Perspectives

As has already been mentioned in the introductory part of this chapter, modern economics does not exist in a vacuum but it is shaped by other disciplines that were not directly linked with economic phenomena in the past. Neuroscience is an example of the domain that is more and more popular in different types of economic research. It has led to the creation of the discipline called neuroeconomics and other economic-related neuroscientific fields of investigation. For example, such subdisciplines as international neurobusiness, international neurostrategy, neuromarketing, neuroentrepreneurship, and neuroethics belong to international neuromanagement. *International*

neurobusiness can be perceived as the neuroscientific dimension of activities, hierarchies, and decisions related to multinational enterprises. Similarly, *international neurostrategy* can be defined as the neuroscientific level of organizational focus on reaching a competitive advantage on international markets. *Neuromarketing*, on the other hand, refers to the neuro side of marketing, represented in using neuroscientific developments and tools in advertising products and services. The more research-oriented perspective of studying the link between marketing and neuroscience is *consumer neuroscience*. *Neuroentrepreneurship*, on the other hand, helps understand the types of entrepreneurs and entrepreneurship and the way biological and cognitive factors determine leadership styles as well as individual and social entrepreneurial activities. *Neuroethics* involves moral approaches to studies in neuroeconomics (Bielenia-Grajewska 2013). Taking the linguistic aspect of neuromanagement into account, the mentioned popularity of neuroscience has led to the emergence of new terms within the economic lexicon that denote the newly created scientific field of neuroeconomics. Thus, such terms as fMRI or galvanic skin response, previously associated exclusively with neuroscience, have been incorporated into the economic discourse of the twenty-first century. Analyzing the rise of interest in the way the brain and the nervous system are influenced by economic stimuli, it can be expected that the economic lexicon will be further enriched with the appearance of even more sophisticated neuroscientific vocabulary.

The Language of Economics and Its Functions

Among its different functions, economic discourse offers successful tools for gaining economic advantage. This phenomenon can be understood in various ways. One of them is to focus on marketing and the way marketing communication shapes customers' behaviors and organizational identity. The linguistic sphere of marketing is visible in, among other things, the creation of brand names and marketing slogans. Moreover, language

is a tool fostering innovation and entrepreneurship, stimulating information flows between disciplines as well as knowledge creation and knowledge communication. In addition, language exhibits the level of knowledge in disciplines (Bielenia-Grajewska et al. 2013). The language of economics serves the communicative function on the inner and outer level of organizations, showing employees how tasks should be done and stimulating effective communication with the broadly understood stakeholders. The language of economics also mirrors the legal dimension of investigated entities. Linguistic policies can be studied by taking into account the micro level, that is, the organization as such, as well as more macro dimensions, such as national linguistic policies or the supranational ones, such as the EU regulations.

The Language of Economics and Methods of Investigation

The language of economics can be investigated by taking into account the methods and tool characteristic of linguistics. Thus, such domains as sociolinguistics, psycholinguistics, neurolinguistics, pragmatics, semantics, and syntax or corpus studies can be used in the discussion on economic communication. The selection of methods applicable to study the language of economics depends on research perspectives. Applying the micro (word) scope, cognitive linguistics may be used to observe the way words are created and understood. Moreover, corpus linguistics facilitates the studies on concordance or collocations. A more macro perspective on the language of economics is offered by discursive approaches, such as critical discourse analysis (CDA). CDA approaches language as a social practice, investigating how language creates social relations and how these relations are perceived by using a selected communicative repertoire. Moreover, critical discourse analysis does not only concentrate on the purely linguistic elements but it also studies nonlinguistic notions to show how both verbal and nonverbal tools determine the interest in the perception, comprehension, and influence of a given economic text. Since CDA is an approach that is used to investigate such

notions as social problems and issues (e.g., dominance or inequality), this method of analysis is used to discuss texts related to economic imbalance, crisis, and corporate changes. Taking into account the growing role of neuroscience in different fields of life, it can be predicted that neuroscientific tools will become even more popular for checking how people create, use, and understand words. Thus, the noninvasive techniques popular in neuroscience, such as fMRI and galvanic skin response (GSR), provide information how an economic term is understood and how the mentioned comprehension facilitates decision-making processes. The language of economics can be investigated by using both qualitative and quantitative studies. Qualitative approaches offer the focus on tendencies and decision-making processes underlying modern economic discourse, such as the use of borrowings or the influence of technology on the way words are created and used. Quantitative studies provide, among other things, statistical data on economic discourse. Researchers investigating the language of economics may rely on methods and tools widely used in the humanities and social studies, such as interviews, questionnaires, expert panels, and case studies.

Conclusion

The multidimensionality of economic communication results in different linguistic and nonlinguistic layers of the phenomenon itself as well as the plethora of approaches that can be used to investigate it. Taking into account the coexistence of economics with other domains of life, it can be predicted that new disciplines will appear that will also focus on the language of economics, at least to some extent. For example, neuroeconomics and neurolinguistics separately and together provide new and complex ways of analyzing how economists speak.

Economic Analysis of Law

Translated by Leah Daniels Simon, Bachelor’s Degree in Law (2014), Universitat Pompeu Fabra (Barcelona).

Definition

Law and Economics is economics applied to the analysis of statutory law systems or subsystems or to legal policy proposals.

Historical Remarks

To talk about Law and Economics or, equally, of the Economic Analysis of Law is to refer to the application of economic science tools to national and international systems of statutory law, as well as to legal policy proposals.

Positive analysis is to be distinguished from normative analysis. Within the framework of positive analysis, economic science is employed within a system of statutory law to explain and predict the consequences of the application of one or more sets of judicial system rules in questions concerning human conduct. It consists, therefore, in elucidating the manner in which people react to the enactment, enforcement, abolition, or reformation of such rules of law. In this sense, the Economic Analysis of Law is a system of theories regarding human behavior. The key question regarding positive analysis is to understand the law as a system of incentives.

Within the framework of normative analysis, on the other hand, economics is applied to the evaluation of rules of law in accordance with the degree to which they contribute to bettering the economic efficiency of the analyzed conduct: given two alternative regulations, the economic normative analysis would give preference to the one whose application, according to predictions based on its own analysis, would generate the most efficient results.

The application of economic tools to the analysis of law is as old as economics itself (Smith 1776). The first systematic applications were focused, understandably, on criminal law (Bentham 1789) – one of the earliest fields in which national legal systems received scientific analysis being that of crime investigation (see the entry ► [forensic science](#)). However, the emergence of the positive-normative movement called Law and Economics took place much later, during

the second half of the twentieth century in the United States of America, driven fundamentally by the influence of academics from the Chicago School. Thus, economists Ronald Coase (1960) and Gary Becker (1968) or jurist Richard Posner (1973) started to massively apply neoclassical microeconomics to law in both analytical and normative terms. In a synthesis reminiscent to European academics of Georg Wilhelm Friedrich Hegel's philosophy, the first Economic Analysis of Law came close to claiming that reality is rational and that rationality must be turned into reality. In Posner's well-known formulation, North American common law is essentially efficient; thus, in the measure in which it has not yet achieved that status, it will end up being so.

Nonetheless, liberally oriented lawyers and economists, such as Guido Calabresi (1961) in the United States or Pietro Trimarchi (1961) and Hans-Bernd Schäfer and Claus Ott (1986) in Europe, were also pillars of the birth of the Law and Economics model.

In the 1970s and 1980s, the Law and Economics movement, as it was defined, was advocated by the best US law schools; however, although the program was also accepted in continental European culture, its penetration in European law faculties was less intense than that which took place on the other side of the Atlantic. See, for instance, Boudewijn Bouckaert and Gerrit De Geest (2000), Peter Cane and Herbert Kritzer (2010), or Régis Lanneau (2014).

The degree of influence of the Economic Analysis of Law program has stabilized since the last decade of the twentieth century; the evolution of Law and Economics has continued to be characterized by its increasing specialization in such a way that currently each legal area or subject possesses top-level economic applications with very rich empirical and econometrical contents. Nowadays, it is inconceivable that a top-level economic analyst specializing in Family Law would also be a specialist, in similar academic conditions, in US Law and the Market of Telecommunications, in the Law of Publicly Traded Companies, in Biopharmaceutical Law, in International Taxation, in Product Liability of Health Agencies, and in International Sales Contracts.

For each and every one of these specializations, readers should consult the corresponding entries of this encyclopedia.

Currently, the level of specialization of economics applied to law and the intensity of its econometric sophistication (see the papers presented at the 24th Annual Meeting of the American Law and Economics Association [ALEA], University of Chicago, 2014, <http://www.amlecon.org/2014-Program.final.revised.pdf>) allow us to state that Law and Economics is a victim of its own success. As it is true of the relationships between Criminal Law, Criminology, and Legal Medicine, or Patent Law and Engineering, along with generalists that hold a good background in economics and a primarily legal education, the different fields within the Economic Analysis of Law would be more ideally developed by multidisciplinary teams in which economists and lawyers collaborate. In the end, as we shall see in this same entry, the specific relationship between economics and law represents a specific instance between the different sciences and the law itself (Lawless et al. 2010).

In any case, and in the current academic environment, top-level North American or European law schools take into account the Economic Analysis of Law and legal institutions although in none of them is the economic and normative Analysis of Law the dominant paradigm.

Legal Assumptions of Economic Analysis

In general terms, economics studies the efficient assignment of scarce resources in specific markets and in the economic system as a whole. Furthermore, political and public sector economics analyze, in a manner independent of market functioning, the feasibility of political and legal proposals regarding wealth redistribution and the establishment of infrastructures or direct public service provisions by governments (Stiglitz 2000; Barr 2012).

In an advanced economy, the objective of economic analysis, i.e., the market, is exogenous to the analytical instruments themselves as well as to their applications, as every market requires some implicit economic assumptions in order to exist,

consisting, at least, of the following two: a system of property rights which formally recognizes who is the owner and what are his or her faculties of use, disposition, and exclusion, and a system of law of contracts that permits owners to exchange goods and services in order to achieve more efficient allocations. In addition to the above, and given a minimally developed economic system, two additional legal systems will be required: Company Law, in particular for limited liability companies and, within these, for publicly traded ones, and, finally, a capital market subjected to one or more public regulations that coordinate, evaluate, and, when applicable, sanction the conducts of those who operate in it (Hadfield and Weingast 2013). These issues do not constitute specific study objectives in any standard economic or microeconomic textbook, but perhaps for this same reason, it is convenient to align economic analysis with the legal assumptions of its own traditional aim (Mankiw 2014; Krugman et al. 2013; Varian 2014; Mas-Colell et al. 1995).

The previous four legal subsystems shape the national or, when appropriate, international systems of private law and are the objective of economic analysis. But, in turn, they also presuppose a public system of legal, governmental, and judicial remedies given the violation of property rights, the breach of contracts, the dysfunction of limited liability companies, or the defective behavior of capital markets. Although it is a fact that the four subsystems have always been partially controlled by social norms, it is also true that, in general terms, private law subsystems depend on public law systems which, operate through coercively adopted central decisions independent of the economic markets.

Economic Assumptions of Legal Analysis

In turn, and in a symmetrical fashion, historical experience substantiates the thesis that a legal system has never been able to survive independently of capital markets or, in other words, the necessity to acknowledge the systematic assignment of economic resources in accordance with the economic analysis itself (von Mises 1920).

From a historical economic point of view, the final destiny of national legal systems depends on their economic successes. The main analytical question continues to reside in the causes of wealth and poverty of nations (Acemoglu and Robinson 2012; Cooter and Schäfer 2012).

Traditionally, as summarized by Polinsky and Shavell (2008), the Economic Analysis of Law has been the target of criticism by those who have pointed out its alleged shortcomings, especially regarding the following three considerations: First, it is at times insufficient and, at other times, inexact to presuppose, as the Economic Analysis of Law would have us do, that individuals and organizations are rational maximizers of well-being. Second, it implies limiting oneself to a positive and normative legal system analysis which takes exclusively into account economic efficiency considerations without regard to the legal consequences resulting from the initial assignment of property rights over production and consumption goods or to the distribution of income and wealth. Third, and lastly, such an analysis would be incomplete if, together with the objective of economic efficiency, it did not take into account criteria of fairness or of basic notions concerning corrective or distributive justice.

The limitations of the neoclassical analysis derived from the assumption of rational human behavior have been corrected, at least in part, by the incorporation of behavioral economics (Akerlof and Kranton 2010; Kahneman 2011; Sunstein 2000). It consists, basically, of enriching the legal analysis with a multidisciplinary treatment of the rules and principles that define it or, in other words, an analysis which is not only economic but also psychological, sociological, and political, as we shall soon see.

As for the criticisms derived from the justice theory or from the lack of attention to particular fairness aspects, it is worth pointing out that the former raise basic economic analysis and jurisprudence issues – jurisprudence being understood as a philosophy of ideas concerning the law without regard to an empirical analysis – while the second criticism often refers to the lack of specific considerations concerning the empirical

consequences that any given regulation could exert on the real distribution of income and wealth in a given society at a specific moment.

The Economic Analysis of Law as an Instance of the Application of the Current State of Scientific and Technological Knowledge to Legal Systems

Economics recognizably forms a branch of scientific activities belonging specifically to that of the social sciences. Within this field, it is part of the formal, natural, and life sciences. Given, then, that law can be analyzed from the perspective of any of the formal, natural, life, or social sciences, as well as from the perspective of technology or the applied sciences to which it is related and not only from an economic standpoint, it is undeniable that to explain and predict the human conduct subject to legal rules, the Economic Analysis of Law is at the same time both necessary and insufficient. For this reason, it can be affirmed that presently the reduction of the analysis of human conduct to economics is no longer endorsed, in the same way that now no one holds the reduction of the analysis of nature to physics (see Schurz 2013).

Therefore, a basic question regarding the relationship between economics and a particular national or supranational legal system is the relevance of a specific social science, economics, in the legal system concerned. Regarding this topic, it is convenient to point out that different national legal systems take into consideration the current state of scientific and technological knowledge in distinct ways and with varying intensity.

To quote an example, the United States' federal law system has, since 1993, established a normative doctrine regarding the consideration an allegedly expert witnesses' testimony should merit to a judge or federal court. The expert is presented before the court itself as a scientist or a technologist, whose aim is to illustrate facts and natural or social issues that might be important to the court for a resolution in which the state of scientific or technological knowledge could be relevant. In

Daubert v. Merrell Dow Pharmaceuticals, Inc., 509 U.S. 579 (1993), a product liability lawsuit, the issue at stake was whether a particular drug had caused or not the damages suffered by the plaintiffs. Given that this matter had a fundamentally scientific basis, the debate was later centered on another issue regarding the reliability, scientific in this case, of the expert witnesses presented by the parties. In this regard, the US Supreme Court established that judges, when faced with scientifically relevant issues and, thus, not subject to the interpretation of the law itself – in other words, out of the realm of their own expertise – should carry out the function of gatekeepers and distinguish between good and junk science. That is, they should exclude a priori witnesses which are purely partial and elaborated with disregard to accepted scientific methods. To that effect, the judge should carry out a preliminary evaluation to determine if the reasoning or the underlying methodologies emanating from the testimony were valid and supported by facts. Firstly, the hypothesis, formulated and presented, should be empirically contrastable – falsifiable, as determined by a then Popperian court. Secondly, the theories or techniques presented to the court should have been subjected to peer review and should preferably have already been published and hence should be accessible to the scientific community. Additionally, the known or potential margin of error should be taken into consideration. And finally, the degree of acceptance of the formulated theories or hypothesis should also be taken into account in distinguishing between good and junk science. The standard established by *Daubert* was later incorporated by the Rule 702 of the Federal Rules of Evidence and has been followed by subsequent cases.

However, not all national legal systems include rules that establish control filters or demarcation operational standards concerning the testimonies of expert witnesses and their scientific or technological reliability. Nor do all national legal systems foresee that before the enactment of a certain statute or regulation, a scientific or technological – and, when applicable, also economical – assessment should necessarily take

place regarding the consequences that the rule would have if it were to be enacted and enforced. Ultimately, the relevance of the Economic Analysis of Law depends on the law itself. To sum up, not everything that is efficient is necessarily fair, but if everything is inefficient, nothing can be fair.

²Max Planck Institute for Research on Collective Goods, Bonn, Germany

Abstract

The roots of law & economics lie in late 19th century Continental Europe. However, this early movement did not persist and was essentially cut short in the 1930s. After World War II, modern law & economics was (re-)invented in the United States and subsequently grew into a major field of research at U.S. law schools. In Continental Europe, law & economics was re-imported as a discipline within economics, driven by economists interested in legal issues rather than by legal scholars. Hence, the European discourse was more strongly influenced by formal analysis, using mathematical models. Today, research in the U.S., Europe, and in other countries around the world, including Latin America and Asia, uses formal, empirical, and intuitive methods. New subfields, such as behavioral law & economics and experimental law & economics, have grown in the U.S. and in Europe during the past two decades.

Definition

A survey of the development of law and economics from the late nineteenth century until today.

Historical Antecedents

Precursors to modern law and economics can be identified as early as the nineteenth century, particularly in German-speaking Europe (Gelter and Grechenig 2007; Grechenig and Gelter 2008 referring to work by Kleinwächter 1883, Mataja 1889, Menger 1890, and Steinitzer 1908). Perhaps the defining piece for this period was the monograph on tort law by Victor Mataja (1888) titled “*Das Recht des Schadensersatzes vom Standpunkte der Nationalökonomie*” (*The law of civil liability from the point of view of political economy*), in which Mataja anticipated central ideas of the American law and economics movement, developed almost a century later. Prefiguring modern law and economics, Mataja focused on the incentive effects of tort law. While the book did not go unnoticed among legal scholars and influenced policy debates, including the drafting of the German Civil Code (Mataja 1889), it had no lasting influence on legal analysis (Englard 1990; Winkler 2004). While the University of Vienna, where Mataja held a position, integrated law and economics into one faculty, and economists in academia were typically trained in law, no law and economics movement developed (Grechenig and Gelter 2008; Litschka and Grechenig 2010).

Generally, one explanation for why the early law and economics movement left no lasting impression is the increasing specialization of the social sciences (Pearson 1997, pp. 43, 131). In the German-speaking countries in particular, legal scholarship remained strongly under the influence of a tradition that had grown out of the nineteenth-century “Historical School.” While conceptual jurisprudence gave way to the more functional jurisprudence of interests, legal scholarship continued to be seen as a hermeneutic discipline focused on a coherent interpretation of the law based on an internal consistency of the system in

terms of language and value judgments (e.g., Grimm 1982, p. 489; Wieacker 1967, p. 443). Policy arguments remained outside of the purview of legal scholarship. Moreover, nascent alternative views that may have led to more openness toward interdisciplinary work, such as the sociological jurisprudence pioneered by Eugen Ehrlich and Hermann Kantorowicz’s “Free Law School,” petered out in the 1930s and were finally cut short by the Nazi regime and World War II. Postwar jurists had no interest in portraying the law as an objective system in order to maintain the legitimacy of the legal profession (Grechenig and Gelter 2008; see also Curran 2001).

By contrast, when the modern economic analysis of law developed in the USA in the second half of the twentieth century, legal theory was far more conducive to integrating interdisciplinary and specifically economic approaches. The Langdellian orthodoxy of the late nineteenth century and the conceptual jurisprudence of the Lochner period up to the 1930s were thoroughly discredited by the legal realist movement. With “the great dissenter” Oliver Wendell Holmes on the Supreme Court as their role model, the legal realists criticized the formalism of the majoritarian jurisprudence, arguing that the law itself was to a large extent indeterminate. As for the rejection of its analogues in Germany, there is also a strong political component to the historical development in the USA: The Lochnerian judges on the Supreme Court defended the previous legal order against interventionist “New Deal” policies of the Roosevelt administration which they declared were unconstitutional. Only when Roosevelt threatened to “pack the court” with more compliant justices this jurisprudence changed, and the realists, who were generally New Deal progressives, won. Even if there was no agreement on the extent of indeterminacy, the insight that judges enjoyed great discretion in interpreting and shaping the law with policy took a strong foothold. The void left by the abandonment of formalism was filled with innovative jurisprudential movements in the second half of the twentieth century, including the legal process school, critical legal studies, and not least law and economics. After 1980, with the older generation of scholars having

left the scene, legal scholars could finally say that they were “all realists” now (Singer 1988, p. 467; Reimann 2014, p. 15). Another important issue was the prevalent role of utilitarian philosophy, on which welfare economics is based, in the US legal discourse compared to other countries (Grechenig and Gelter 2008, pp. 319–325). Finally, the maturation of economics as a discipline meant that it was better equipped for addressing legal issues than it was in the late nineteenth century (Litschka and Grechenig 2010).

The Development of Modern Law and Economics

The contemporary law and economics school is typically traced back to around 1960, specifically to the work of Ronald Coase and Guido Calabresi (e.g., Schanze 1993, pp. 2–3). However, from an institutional perspective, the basis was laid at the University of Chicago in the 1940s and 1950s, when economists first taught at the law school. Most prominently, Aaron Director began to teach at Chicago in 1946 and initiated interdisciplinary discussions both inside and outside of the classroom, most significantly in antitrust law (Duxbury 1995, pp. 342–345). He was the first editor of the *Journal of Law and Economics*.

The development of a “law and economics movement” can probably be credited to the publication of Ronald Coase’s “Problem of Social Cost” in that particular journal in 1960 (Coase 1960). The article’s core insight about the reciprocity of the relationship between the tortfeasor and the victim, and hence the significance of transaction cost, helped the economic method to expand into fields where the application of economic principles did not seem immediately obvious, such as contract or tort law. In this intellectual climate, other economists developed economic theories pertinent immediately to legal questions. Gary Becker of the Chicago economics department can be credited for applying economic principles to crime (Becker 1968), racial discrimination (Becker 1957), and family life (Becker 1981).

The prominence of the economic analysis of law in the USA today, however, probably must be

attributed to its adoption by *legal* scholars, for whom the law is – other than for most economists – the primary field of research. Among these, Guido Calabresi, Henry Manne, and Richard Posner stand out as some of the pioneering law and economics scholars.

Yale professor (later federal judge) Calabresi, in 1960, apparently independently from Coase, began a research program that led him to publish a series of articles on tort law, in which he explained its structure on the basis of simple economic principles (Calabresi 1961, 1965, 1968, 1970, 1975a, b; Calabresi and Melamad 1972; Calabresi and Hirschhoff 1972).

Henry Manne, who worked in corporate and securities law, critiqued the wisdom prevailing in these areas from the 1960s onwards (Manne 1962, 1965, 1967), attracting particular attention for his view that insider trading should be legal (Manne 1966a, b). He succeeded in transforming the George Mason University’s fledgling law school into a law and economics powerhouse (see Manne 2005). He established intensive courses on microeconomics for judges and for law professors. The fact that about 40% of federal judges had taken such a course by 1990 helped the acceptance of law and economics in the courts (Butler 1999).

Richard Posner, as a young professor at the University of Chicago Law School, not only established the *Journal of Legal Studies* in 1972 but became a trailblazer within legal academia by publishing the first edition of his monograph *Economic Analysis of Law* (Posner 1973). This standard text was the first to subject almost the entire legal system in its full breadth to a systematic analysis from an economic perspective. Posner’s publication output, both before and after joining the federal bench, is unparalleled, as he continued to influence the development of both the law and legal scholarship with his articles, books, and opinions. One of the most noted ideas was the theory, originally proposed in his textbook, that efficiency (largely defined as wealth maximization) could explain the structure of the common law across the legal system. Given that an inefficient precedent was likely to be questioned and subsequently overruled, in this view the common law tends to develop efficient solutions in the long run (Posner

1979, 1980). Obviously, the thesis has remained controversial, both as a descriptive account of the common law and as to whether wealth maximization should, normatively, be the objective of policy analysis in law (see Parisi (2005, pp. 44–48) for a summary of the debate).

Continental Europe has been described as lagging behind the USA by at least 15 years in terms of the development of law and economics (Mattei and Pardolesi 1991). While law and economics has been growing steadily in Continental Europe since the publication of Schäfer and Ott's textbook in 1986 (Schäfer and Ott 1986), important differences remain in both the methodological mainstream approach and the quantity of law and economics scholarship published in domestic law reviews. Scholars have attempted to explain the divergence by institutional factors at university level, such as publication incentives, hiring policies, and the legal curriculum (Gazal-Ayal 2007; Garoupa and Ulen 2008; Parisi 2009), on the one hand, and the institutional environment on a state level, including the separation of the legislature and the judiciary and legal positivism (Kirchner 1991; Weigel 1991; Dau-Schmidt and Brun 2006), on the other. Others have extended these approaches and focused on the legal discourse that was connected to the institutional setup. Since the Continental European concept of a separation of powers implies that a judge may only "interpret" the law, policy arguments such as those provided by law and economics were outside the scope of the legal discipline. To the extent that the legal discourse allowed for policy arguments, European legal doctrine was more strongly based on deontological philosophy than scholarship at US law schools (Grechenig and Gelter 2008).

Maturation into an Established Discipline

In the USA, economic analysis became one of the main methods of legal scholarship – both descriptive and normative – in legal academia. Other than in the early twentieth century, and in sharp contrast to Continental Europe, law is not recognized

as an autonomous discipline but a field to be studied from various social science perspectives (Posner 1987). Leading law schools often hired economists to teach and research in the area of economic analysis of law, and in the course of the 1980s and 1990s, the number of faculty with an interdisciplinary background, e.g., with a J.D. and a Ph.D. in Economics, increased (e.g., Ellickson 1989). While some legal academics publish in economics journals or in specialized law and economics journals where formal modeling or econometric analysis is typically required, a lot of economic analysis of law takes the intuitive, non-formal/non-mathematical form that is acceptable in law reviews, and one does not necessarily need to be a trained economist to be able to follow the law and economics approach.

In contrast, European law and economics scholarship was more formal (both theoretical and empirical) and was primarily driven more by economists – a characterization that remains true today (Depoorter and Demot 2011), even though non-formal law and economics scholarship at law faculties continues to grow. Several universities (primarily in the Netherlands, Germany, and Italy) have established research centers for law and economics; there are also a number of public research institutes with a strong focus on law and economics, such as the Max Planck Institute for Research on Collective Goods in Bonn, which emphasizes experimental research, and private initiatives, e.g., the Center for European Law and Economics (CELEC). Several professorships for law and economics have been established, for example, at the Universities of Amsterdam, Bonn, Frankfurt, Hamburg, Lausanne, and St. Gallen as well as at the EBS. International programs for the study of law and economics (EMLE, EDLE), both at undergraduate and at graduate level, allow students to specialize at the intersection of the two fields. An increasing number of national programs complement the options students have today. From a historical perspective, the European Association of Law and Economics (EALE), founded in 1984, seven years before the formation of the American Association (ALEA), has played an important role in the emergence of law and economics. A significant number of national and

international associations for law and economics have been established since, including in Latin America (Latin American and Iberian Law and Economics Association – ALACDE), Asia (Asian Law and Economics Association – AsLEA), Israel (Israeli Association for Law and Economics – ILEA), and other non-European countries, as well as in several European countries. These associations typically hold annual conferences, facilitating the cooperation between law and economics scholars. Today's conferences and meetings are typically more formal in terms of research methods than they used to be, although some meetings, for example, in Latin America, focus on non-formal methodology (a verbal, law-review style). An increasing number of law and economics journals, textbooks, and treatises have become available as publication outlets. Since the beginning of law and economics scholarship, research has risen to a countless number of associations, conferences, articles, etc. As a consequence, some scholars have claimed that the divergence between European and American law and economics has become much smaller than often perceived (Depoorter and Demot 2011). However, it is certainly fair to say that the influence of law and economics on the mainstream legal discourse is still much larger in the USA than in Europe. Scholars continuously argue that courts outside the USA rarely take economic consequentialist arguments and empirical evidence into account (Grechenig and Gelter 2008; Petersen 2010).

New Developments in Law and Economics

Current law and economics incorporates much of the critique that has been brought forth throughout the past decades, for example, regarding the notion of efficiency. While the traditional rational-choice approach still plays an important role, there is a growing literature on behavioral and experimental law and economics (Jolls et al. 1998; Sunstein 2000; Gigerenzer and Engel 2006; Engel 2010, 2013; Towfigh and Petersen 2014). One of the most notable movements

includes empirical legal studies. With the formation of a Society for Empirical Legal Studies (SELS), the launch of the *Journal of Empirical Legal Studies* (JELS), and an annual Conference on Empirical Legal Studies (CELS) (all between 2004 and 2006), this field became an important discipline closely connected to law and economics. Behavioral economics and empirical legal studies have helped the economic analysis of law broaden its scope by including studies with field data and experimental data, for example, experiments with judges (e.g., Guthrie et al. 2001) and laboratory experiments that demonstrate how humans behave under legally relevant circumstances (McAdams 2000; Arlen and Talley 2008; Engel 2010). Recently, a professorship for experimental law and economics, held by Christoph Engel, was established at Erasmus University in Rotterdam. The coming decades will show the way to a closer connection between the two disciplines and an enhanced use of economics in legal research, making use of whole spectrum of economic methods and possibly extending to new fields such as law and neuroeconomics.

Laboratory, Metz, France

Abstract

“Law and finance” is a rather new and evolving research topic, initiated by La Porta, Lopez-de

Silanes, Shleifer, and Vishny (henceforth LLSV). They investigated the differences between legal origins and their impact on economic performance. Two seminal papers published by LLSV in 1997 and 1998 addressed an important question: Does law matter? Their main idea was to evaluate the impact of legal protection of investors (shareholders and creditors) on three key areas: corporate governance, structure of ownership, and control and orientation of financial system. Their work was extensively referred by other researchers and is now considered as a new finance theory. So as the reader is able to appreciate the nuances of the theory which was postulated by LLSV, we propose a two-step approach: first, a detailed description of the theory which would be followed by a summarized discussion of related works on law and finance.

Law and Finance Theory: Contribution by LLSV

Based on a sample of 49 countries, LLSV had investigated the differences between the four legal origins: common law, French civil law, German civil law, and the Scandinavian civil law.

The common law which originated in England provides great flexibility to its judges. They can administer a case according to their discretion, and the outcomes can vary on a case to case basis, as long as the judgments are fair and in conformity with the law of precedent. The civil law was pioneered in France and is replete with statutes and written codes. Herein, judges cannot act with full liberty to exercise their discretionary power. (French civil code is a derivative of the Napoleon Code of 1804. Its main objective was to standardize laws. However, the German civil law of 1896 differs from the civil code due to its different origins. Similarly, Scandinavian civil law differs from both the French civil law and common law. Most of the countries, according to La Porta et al. (1998), were categorized into one of the four aforementioned and dominant laws.)

Law and Finance, Table 1 “Rule of law” within common and civil law countries (The data was collected between 1994 and 1995)

Legal origin	Number Of countries	Shareholders' rights	Creditors' rights	Rule of law
Common law	18	4	3,11	7,11
French civil law	21	2,33	1,58	3,91
German civil law	6	2,33	2,33	4,66
Scandinavian civil law	4	3	2	5
International mean	49	3	2,3	5,30

The empirical comparative studies of LLSV (these papers were published in 1997, 1998, 1999, and 2000), used an indicator called “rule of law” (Table 1) which measures the legal protection of the minority investors and is an aggregated indicator of ten dummy variables: six of which describe the rights of shareholders and four describe the rights of the creditors. Each dummy variable has a value of 1 if the right is valid within a country and 0 if not. These rights represent many aspects of the law such as security exchange, bankruptcy, corporate law, and commercial code.

Their main results postulate the idea that common law countries generally provide better investor protection than civil law (French, German, and Scandinavian) countries whereas French civil law countries provide the least level of investor protection.

In order to evaluate the impact of law on financial and economic systems, LLSV used the legal investor protection variable for explaining the differences between all 49 countries of their sample with regard to (1) corporate governance, (2) structure of ownership of firms, and (3) structure and development of financial systems.

Law and Corporate Governance Models

LLSV proposed a new approach to corporate governance. If we consider corporate governance as a set of internal and external mechanisms which promote the efficiency of a corporation, then the legal system approach is a constituent of the external mechanisms. It is defined as a set of rules conceived to protect outside investors, in minority, against managers, the board of directors, and stakeholders. Hence, the need to integrate a sound legal structure and an effective form of corporate

Law and Finance, Table 2 Shareholders rights and structure of ownership and control

Shareholders rights index	Widely held firms	Families owned firms	State-controlled firms
High level	47,92%	24,58%	13,75%
The USA (5)	0,80	0,20	0,00
The UK (5)	1,00	0,00	0,00
Low level	27,33%	34,33%	22%
France (3)	0,60	0,20	0,15
Germany (1)	0,50	0,10	0,25
Finland (3)	0,35	0,10	0,35
Mean of the sample	36,48%	30%	18,33%

governance becomes imperative, even more amidst the wake of the failures of multinational firms such as Enron, Vivendi, Parmalat, etc. Similarly, bankruptcy laws are crucial in the prevention and resolution of financial distress of corporations.

Law and Structure of Ownership and Control

From a list of 27 richest countries (LLSV chose 27 richest countries based on the income per head in 1993), LLSV (1998 and) used a sample of 20 large private and nonfinancial firms for their analysis (Table 2).

LLSV divided their sample of 27 countries into two groups: one group with high level of legal protection of shareholders and the second with low degree of protection.

They concluded that a high level of dispersion of ownership and control is observed within countries offering good shareholder protection (as the USA and UK). It was observed that the percentage of large companies which were characterized by a dispersed shareholding was 47.92% in the first group and 27.33% in the second group.

Legal Structures and Development of Financial Systems

LLSV established an empirical correlation between the share of external financing (bank debt and equity) in the total financing of firms and the structure of the legal system. They observed that the common law countries have higher levels of financing by market capitalization as compared to civil law countries, particularly the French civil law countries. They demonstrated that countries that offer better protection to the shareholders benefit from more developed financial markets and a greater number of stocks per capita. Similarly, an important legal protection of creditors involves a developed banking system. In general, the common law countries have market-based financial systems, and civil law countries have bank-based systems. At the same time, LLSV remark that French civil countries are financially less developed than common law countries (Table 3).

The seminal papers of LLSV have been the subject of many criticisms and extensions. We will first present the principal critics and then the proposition for an extension of this legal approach. We can safely concur that these works are encapsulated within the framework of law and finance literature and have in their own rights the capacity to be termed as a new financial theory.

Law and Finance, Table 3 Investor protection and structure and development financial system

Countries	Market capitalization/ GNP	Number of listed companies per capita	Bank ^a
Common law	0,60	35,45	0,83
French civil law	0,21	10,00	0,67
German civil law	0,46	16,79	0,92
Scandinavian civil law	0,30	27,26	0,90
Mean of the sample	0,46	21,59	0,83

^aBank = the ratio of bank loans compared to the sum of assets related to domestic credit of the central bank and bank lending (Levine 1998)

Scope of the Literature of “Law and Finance”: A Critical Analysis

The work of LLSV, however, has also been the focus of much criticism. In particular, two groups of studies are worth a mention in our analysis and postulation. On the one hand, there is a group of several studies which presents the critical analysis of their methodologies and its deficiencies while offering alternative methodologies. These studies constitute the main core of “law and finance” literature. On the other hand, there is a second group of studies which offers critical insights into the theoretical aspects of the work of LLSV and tries to elaborate on their work. This kind of work is contributing to the growth and development of a “new political economy” theory.

A Critical Approach of LLSV’s Methodology

These types of articles proposed that LLSV’s seminal works have significant legal deficiencies of theoretical and empirical statures that are highlighted in several recent studies designed to challenge their main conclusions. We can segregate such papers into four categories:

1. *The legal indicators built by LLSV are composed of only ten rights of investors:* Many articles point out the fact that the postulated ten rights are not sufficient to effectively describe the national legal protection of investors and a legal system in entirety. Then several papers propose new legal indicators based on largely more than ten rights (e.g., Pistor et al. (2000)). Also, Holderness (2006) highlights that LLSV’s use of aggregated data, in particular, the indicator of the degree of concentration of ownership. According to LLSV, the latter is explained only by the legal system (national factor) and is not influenced by other factors (firm size, age, etc.).
2. *LLSV’s studies are cross-sectional studies:* This is also the case of many studies using legal indicators of LLSV, such as the “doing business” annual reports published by the World Bank. (WORLD BANK, DOING BUSINESS REPORTS (since 2004), available at <http://www.doingbusiness.org>.) Indeed, in

order to attribute scores of an annual growing sample of countries, the World Bank measures the “rule of law” with respect to a large number of countries all over the world. However, this method neglects the dynamic aspect of legal factors. Many studies have proposed more sophisticated legal indicators as compared to LLSV. Some of them focused on the time series data with respect to one particular country, while the others took multiple countries into account. For example, the research conducted by Hyytinen et al. (2003) about Finland shows the evolution of legislation over the period 1980–2000, particularly after the financial scandals. The authors find that the improvement of shareholder rights leads to restructuring of the financial market. Changes in investor protection are, therefore, a by-product of financial market development. And, similar conclusions are obtained by studies conducted on other countries, especially the ones with French civil law.

3. One of the criticisms of LLSV’s works is that their idea was to prove the legal and financial superiority of common law countries as compared to civil law countries. In order to challenge this conclusion, Blazy, Boughanmi, Deffains, and Guigou conducted a study in 2011 and found that the legal protection of investors in France is not as bad as presented by the works of LLSV, especially when we consider the dynamics of the evolving law and financial structures and the ability of the French system to quickly adapt progressively to the changing reforms. The highlights of this study demonstrate that study of LLSV is a relatively descriptive work used in order to prove some normative hypothesis.
4. *The classification of countries according their legal origins*: Common law versus civil law is deeply criticized. Modigliani and Perotti (2002), contrary to LLSV, base their analysis not on the legal origin but on the quality of legal rules. They thus prove the superiority of civil law countries as compared to Scandinavian Anglo-Saxon countries with regard to their impact on the quality of law enforcement on financial development. From a general point

of view, an international comparison of investor rights similar to those carried out by LLSV but on more recent data may not reach the same conclusions. This assumption is justified by the evolution of legislation in several countries, particularly following the recent financial scandals.

Ultimately, the LLSV vision is based on a “shareholder value” whose objective is to maximize shareholder value of the company. In these conditions, the superiority of common law countries with those of codified law is justified only by the higher level of legal protection of shareholders in the former than in the latter. Their results can be mitigated if we consider the “stakeholder value.” In this model, the objective is to maximize the total value of the company. The interests of all stakeholders are taken into account. Shareholders are set to the same status as other stakeholders (employees, customers, suppliers, etc.). An empirical study conducted by the OECD (1999) in fact shows the existence of two groups of countries. On the one hand are countries of continental Europe and Japan that are characterized by high protection of employees and low investor protection, while on the other hand are the USA and Great Britain where the reverse situation is observed (Pagano and Volpin 2001).

Theoretical Critic Research: The Political Theory

Some authors believe that political theory is more compelling to explain financial and economic development than the law and finance theory. Also, we can decide to classify these works as taking part of the “law and finance” theory.

Thus, the main idea of these critics’ articles is that financial development cannot be exclusively explained by legal origin theory, because the financial systems are evolving rapidly, while the legal origin remains stable and evolves languidly. In addition, the structure of the financial system has evolved over the last century. This change has been effected more by political lobbying, than by legal reforms (Rajan and Zingales 2001). Thus, the political theory raises the following questions: Why and how can the political process influence

financial systems? Is the effect of the political process on financial development more remarkable than the legal system? LLSV neglects the political aspect in their explanation of the superiority of common law as compared to civil law. They do not consider that the judges of common law countries may want to serve political interests. The political aspect is an important factor in the analysis of financial development and economic performance. Several studies are based on the proposition that political factors influence corporate governance, not only through the law but also through other channels of transmission. LLSV approve the idea but argue that the law remains the principal transmission channel through which politics affects corporate governance. The political theory is built around two axes. The first is represented by an economic approach called the "New Political Economy." The second axis is constituted by an ideological inspiration "the 'ideological' political theory."

The New Political Economy

This approach aims to provide some answers to two main questions. First, it seeks to understand why the regulations of financial systems are often imperfect and reduce the development of financial markets. On the other hand, it seeks to determine as to why some countries are characterized by inefficient financial institutions or by low-quality implementations of financial regulations. This new theory of political economy, initiated by Pagano and Volpin (2001), addresses these questions using the economic analysis methods. Originally, political economy focused on the interconnection of politics and macroeconomics. The New Political Economy, however, aims to analyze the political interference in the financial market. History bears testimony to the fact that political intervention in the financial market is not confined to periods of crisis and economic depression. Indeed, political pressure from special interest groups and politicians' concerns about the progress of their careers lead to specific policy interventions in financial markets such as nationalization, privatization, etc. (Pagano and Volpin 2001). This raises the question of how interest groups can influence the rules of law through the

political process. The LLSV's legal argument is based on the idea that law is an exogenous factor of financial development. The policy approach outlined by Pagano and Volpin (2001) however requires that the degree of protection of investors and the quality of enforcement of the law cannot be considered as exogenous variables. In fact, the political process has an impact on the development of legal rules and on their applications. Thus, in order to maximize their economic performance, voters (individuals or firms) form interest groups. These groups influence politicians who will therefore introduce the legal reforms required and suggested by the interest group voters. These reforms will therefore influence the economic results in favor of interest groups. (We can hold the same reasoning within corporations: stakeholders can prefer a low level of legal protection of minority investors; actually they can expropriate them easier. Then, they can appeal to the help of employees in order to require a weak protection to minority shareholders. This can work only when employees are not shareholders of the firm (Pagano and Volpin 2001).) On the other hand, holding a significant stake in the firm by the directors may constitute a solution to the problem of expropriation of minority shareholders by the stakeholders (LLSV 1999). When the manager is himself a shareholder, conflict of interest between shareholders and the manager is reduced.

An empirical study conducted on some OECD's countries classifies the sample into two groups: a group of "corporatist" countries and another composed of non-corporatist countries. In the former, the level of protection of employees is high to the detriment of investors. In contrast, the latter giving more importance to investors. Pagano and Volpin noticed that this classification is the result of the political process influences that determine the orientation of a country toward better protection in favor of employees or in favor of shareholders. The potential cost of corporatism may be a low level of external funding and underinvestment. Therefore, the arrangement creates a social inefficiency *ex ante*. Indeed, minority shareholders (with no control rights) do not want to take the risk of being expropriated of their funds by insiders. This rationing of capital

can be very expensive for new companies looking for funding (Pagano and Volpin 2000). The differences in terms of corporate governance, between continental Europe and the USA, can be explained by the fact that in the latter there are no shareholders holding control blocks. In contrast, in continental Europe, they, as employees and firms' managers, are insiders. Accordingly, the managers of American firms have more influence on politicians so they can better safeguard their revenues. This may explain the different waves of regulations in the USA to restrict the power of bloc-blocks of ownership and control of firms (Roe 1994 and Roe and Bebhuk 1999). It follows that the political forces influencing the structure of control rights and corporate finance. The balance of power between different stakeholders (the majority shareholders, minority shareholders, managers, and employees) determines the relative weight given by the firms in terms of the profits to shareholders and well-being of employees. The political factor also affects the development of banks. Policy reforms intended to increase the legal protection of creditors may induce a reduction in the work of selecting borrowers. A reform that aims to increase the efficiency of the legal system may encourage banks to reduce the frequency of verification of the results of borrowing.

The "Ideological" Political Theory

Initiated in 1999 by Roe, this approach assumes that policy choices that determine the protection of investors and the quality of its implementation are driven by ideological factors. Indeed, Roe (1999) emphasizes that the different models of corporate governance between the USA and the countries of continental Europe are the result of an incompatibility of the American ideology with specific social democracy European countries. According to Roe, European states must maintain a social pact between all classes. The question that arises is why this thesis based on the ideological factor paves a prominent place for the political process. Given the fact that ownership is concentrated in the most developed countries, Roe (2001) assumes that the political factor has an impact on the ownership structure. The

governments affect the concentration of ownership of firms in countries of continental Europe. In contrast, in the USA, the low level of government's intervention has eased the development of the managerial firm. According to Roe, in a social democracy, the social factor is clearly present. Indeed, politicians encourage the directors of firms to ignore the interests of shareholders in order to preserve those of employees and not dismiss them. In these circumstances, the directors submit easily to political interference and pressure. However, this intervention does not lead to the same result when capital is concentrated. Indeed, majority shareholders do not yield so easily to the pressures of politicians because of their financial goals tied to their firms. By influencing corporate governance, political leaders of socially democratic countries induce more agency costs (compared to control costs incurred by minority shareholders of the managerial firms). As a result, minorities opt for the concentration of ownership in order to be blockholders of control. To test these predictions, Roe undergoes an empirical study based on 16 countries of different political outlooks. The main conclusions are the influence of political positioning is confirmed, and countries with "left" politically position have corporations with high level of ownership concentration. In the USA, a low level of concentration of ownership is a striking characteristic of the firms.

The results of the ideological approach of the political theory demonstrate that the continental European countries, characterized by a social democracy, seem less effective than the USA in terms of dispersion of ownership. The governments of socially democratic countries may create gaps between shareholders and managers and employees, and consequently managerial firms find raising external capital relatively cumbersome in these countries. It is noteworthy that empirical studies found out that until the early twentieth century, a capital market more developed than the US capital market characterized France. However, this trend was reversed in the 1980s. In recent years, the differences between the two countries are not clearly evident. Hence, the discrepancies that may exist between these two

countries may not necessarily determine the superiority of one over the other.

Roe notes that in the socially democratic countries, stability may compensate the loss in efficiency caused by the weak protection of shareholders and that over a long period these countries have a high level of productivity. The author explains the specificity of social democracies using an analysis in terms of “path dependence.” He believes that continental European countries cannot neglect the social factor because of the influence of past wars and encourages them to opt for social stability. The ideological approach is focused on the fact that the solution to problems, caused by the opening of capital of firms and the willingness to develop market economy, can provide stability to their political and social structure. Solving these problems is not only limited to setting up a legal environment. Legal reforms must also be accompanied by political reforms to further develop the financial markets and foster economic growth.

The ideological approach of the political theory differs from that of the New Political Economy. According to the latter, the degree of legal protection of investors is the result of the economic interests, as it assumes that political decisions are influenced by economic interests and not by ideological and social factors. However, it is difficult to distinguish those ideological political choices from economic political choices.

Conclusion

The “law and finance” literature integrates the legal factors into the analysis and thus provides answers for three basic questions: the explanation of the differences between (i) the structures of ownership and control, (ii) modes of corporate governance, (iii) and the development and organization of financial systems. The several empirical studies conclude the existence of two types of legal origins (civil law and common law). Based on the idea of the superiority of common law, the seminal papers (LLSV) deduce a number of

results on corporate governance and the development of financial systems. First, they challenge the widely held model described by Berle and Means (1932) by showing that it is only representative of few number of countries. Indeed, they highlight the existence of a strong propensity of companies with a concentrated family shareholding. Second, the proponents of the “law and finance” theory note that the dispersion of ownership and control is a proof of the strong protection of minority shareholders.

Third, this legal approach shows that common law countries are characterized by a model of corporate governance that is exercised primarily through the control of external shareholders. In civil law countries, the companies are controlled internally by its main shareholders.

Fourth, the legal approach empirically verifies the hypothesis of a relationship between the legal system and financial development. It highlights that those countries that provide better protection to shareholders (common law countries) as compared to those who do not (civil law countries) enjoy a better-developed market economy.

Fifth, the legal approach leads to the conclusion that legal protection of investors must be represented by not only the content of legal rules but also the efficiency and quality of their enforcement.

Finally, the legal approach of LLSV is the subject of several theoretical and empirical critics. The main one is the political theory. The political theory is built around two axes. The first is represented by an economic approach called the “New Political Economy.” The second axis is constituted by an ideological inspiration “the ‘ideological’ political theory.” The main argument of the first is that the degree of investor protection and the quality of enforcement of the law cannot be considered as exogenous variables in the functioning of the financial system. The second approach excludes the legal factor and explains the legal differences between countries in terms of financial development, by ideological factors.

We note also that the framework of law and finance theory is extended around many other axes. Indeed, many studies are based on “stakeholder” perspective that extends the analysis to

include the legal protection of employees and bondholders and not only shareholders. In addition, we include within the “law and finance” literature many studies that provide a more comprehensive view of distressed firms and bankruptcy. These studies are based on new methodology that provides several legal indexes used to describe bankruptcy law. Thus, they provide a more comprehensive view of bankruptcy than that proposed by LLSV, who were built upon four legal indexes that mainly focused on secured creditors’ rights and studied only the reorganization procedure, while the majority of bankruptcies end up in liquidation procedure (see Blazy et al. (2012, 2013)).

Definition

Legal aid is a type of financial aid in which the State bears the costs of litigation to allow the

poorest people access to the courts. It therefore reduces the litigation costs borne by the beneficiary litigant. It may thereby have an impact on the litigants' behavior (decision to sue, dispute resolution procedure, precaution taking, incentive to engage in a criminal activity). It may also have an impact on lawyers' activities and the effort they devote to defending their clients' interests. It may therefore be useful to compare this method of financing access to justice with other possible alternatives, such as contingent/conditional fees and legal expenses insurance.

Abstract

Legal aid is a financial aid of the State to make access to justice for poor people easier. Law and economics scholars study its impact on the litigants' behaviour (decision to sue, dispute resolution procedure, precaution taking, incentive to engage in a criminal activity) but also on lawyers' activities. Finally, legal aid is compared with other possible alternatives, such as contingent/conditional fees and legal expenses insurance.

Introduction

Legal aid (LA) conforms to the principle of solidarity and the obligation, imposed at European level by the European Court of Human Rights and the Court of Justice of the European Union, to allow all citizens to defend their rights through the courts. The methods used to grant aid vary from one country to another but are generally based on the beneficiary's financial resources (upper limit of income) and, under certain circumstances, the merit of the case. LA may be proportional, if it covers a percentage of the expenses incurred by beneficiaries for the defense of their rights (percentage of up to 100%), or granted on a flat-rate basis if beneficiaries receive a fixed amount (corresponding to the payment of a certain number of hours to the lawyer or to funding a specific stage of the litigation) and then have to cover other additional expenses. It may cover the

costs incurred for a dispute in civil as well as criminal matters.

The economic literature devoted to LA is quite insubstantial, and the studies mainly concern England and Wales (Rickman et al. 1999), Scotland (Stephen 1998, 2001), France (Doriat-Duban 2001; Ancelot et al. 2012), and occasionally European countries (Lambert and Chappe 2014). All of these studies are based on the premise of a growing and continuous increase in spending on LA in the justice budget. They mostly have two separate aims: to explain the growing recourse to LA and to understand how LA affects the behavior of the parties (beneficiary, lawyer, and defendant). The insight they provide may thus be useful for public policies seeking either to reform LA or replace it with other methods of financing access to justice (contingent/conditional fees or legal expenses insurance).

Impact of LA on Access to Justice and Effectiveness of the Law

LA may be granted in civil or criminal cases.

In civil matters, the studies focus on the influence of LA on incentives to sue, dispute resolution procedure, and damage prevention. In a model based on the optimism of the parties, Doriat-Duban (2001) shows that LA increases the number of legal proceedings by reducing the costs of access to justice. Nevertheless, if it allows for the payment of lawyers' fees when a transaction is concluded before the seizing of a court, then the frequency of prosecutions will fall, and the prevention and compensation of damage will rise. As far as the dispute resolution procedure is concerned, the impact of LA seems uncertain because two effects are exerting opposite influences: the drop in negotiation costs increases the chances of an amicable settlement and the decrease in litigation costs increases the probability of judgment.

More recently, Lambert and Chappe (2014), in a model with asymmetric information, have studied the effect of LA on incentives to take precautions, the decision to take legal action, and the amount of the expenditure incurred by the plaintiff in proceedings. They show that flat-rate or proportional LA has a positive effect on

incentives to sue and, in advance, on incentives for potential perpetrators of damage to take precautions. However, the impact on the number of litigation cases is unclear because everything depends on the dominant effect, from a rise in number of prosecutions to a drop in the number of accidents.

In criminal matters, Garoupa and Stephen (2004) mention that three theoretical arguments against LA are traditionally put forward: it may have a negative effect on deterring people from committing crimes by reducing the costs of their defense; it could be a source of inequalities in the sanctions expected for the same offense; and it could be replaced by a more effective income-based subsidy. Nonetheless, the authors present an argument in favor of LA. To this end, they consider it not merely as an expense in the State budget but as a public subsidy contributing to the optimal application of justice. More specifically, in the event of miscarriages of justice, LA improves the situation of all defendants (innocent and guilty) because it reduces the marginal cost of their defense; but as a guilty party is presumed to be more likely to plead guilty than an innocent party, its effect is to provide more help for the defense of innocent parties. If this effect was sufficiently pronounced, then governments wishing to maximize social well-being would be well advised to implement a LA system. This argument is strengthened if subsidizing the expenditure on defense reduces the sanction incurred by innocent parties by allowing them to improve their defense.

Impact of LA on Lawyers

A recurrent question on LA concerns its growing budgetary burden: whereas certain authors mention the very steep rise in expenditure on LA (Gray 1994; Stephen 1998, 2001; Goriely et al. 1997; George 2006), others explain this rise as a problem of moral uncertainty linked to its attribution methods in the majority of countries in which the legal institution (the principal) delegates to the lawyer (the agent) the power to decide whether or not to defend a case and the number of hours to devote to it. However, the combination of asymmetric information and different incentives for

these two parties generates opportunistic behavior in lawyers. Furthermore, LA could remove the incentives for clients to monitor the amount of effort their lawyer devotes to their defense (Bevan et al. 1994). The massive rise in expenditure on LA that began in the 1980s would therefore be due to a supply-induced demand, with the lack of opportunities for lawyers in privately financed cases having increased the relative attractiveness of cases financed by LA (Bevan 1996).

Extending this analysis, Gray et al. (1999) sought an empirical link between the increased expenditure on LA and the supply of lawyers' services. In particular, they set out to determine whether lawyers adjust the level of their service according to their opportunity costs. The attention paid to lawyers' efforts is justified for two reasons: one is theoretical linked to the aforementioned moral uncertainty, and the other is empirical linked to the concomitant rise in public expenditure on LA and in the number of lawyers (in England and Wales). In this way, lawyers may have been able to make upward adjustments to the services provided in the context of LA, due to the drop in the opportunity costs that might have been represented by relinquishing activities previously carried out on a monopolistic market that is now open to competition. In other terms, as the other cases became less lucrative, those covered by LA became relatively more attractive. Different elements are then identified as possible explanations for the rise in spending on LA, including the volume of disputes and the unit cost of each case, for a given region. The volume of disputes depends on the number of cases covered by LA and the number of lawyers (or firms) handling these cases. The unit cost of the cases depends on the number of hours of work provided by the lawyer and the hourly rate applied. If this rate is assumed to be constant, then only two variables can explain variations in the unit cost: an "input" effect reflecting the variation in the number of hours devoted to a case and a "volume" effect reflecting the change in the number of cases handled by a firm, in the presence of diseconomies of scale at the regional level. In addition, the unit cost may increase for two other reasons: the

arrival of relatively inexperienced lawyers on the market which reduces economies of scale and experience effects and the fact that in response to heightened competition, firms are accepting cases of lesser merit to which they are devoting greater effort. This empirical analysis therefore shows that lawyers may increase the budgetary cost of LA, irrespective of the preferences of their clients and the public authority, especially if little monitoring is carried out.

LA Versus Other Methods of Financing Access to Justice

In view of the different effects of LA identified by the economic literature, consideration should be given to its possible alternatives. This raises the question of the consequences of transferring State-funded litigation expenditure to another agent: the lawyer in a system of contingent or conditional fees and the insurer in a legal expenses insurance system.

Concerning transfer to lawyers, Lambert and Chappe (2014) compare the effects of LA with those of contingent/conditional fees. They show that the probability of prosecution is higher in the second case, insofar as the plaintiff bears no expenditure and consequently no risk, which is borne by the lawyer. However, for a given expenditure borne by the plaintiff or lawyer, LA allows for an increase in expenditure on the proceedings, which increases the probability of the plaintiff winning and, in advance, also increases the incentives for the potential perpetrator of damage to take precautions.

Concerning transfer to insurers, both LA and legal expenses insurance tend to strengthen the plaintiff's negotiating position: by covering some or all of the litigation costs, they encourage him/her to demand more in order to abandon the litigation. Nevertheless, as explained by Ancelot et al. (2012), this heightened risk of congestion of the courts is reduced if account is taken of the agency relationships forged in adversity and the possible benefits for lawyers of coming to an amicable settlement. In addition to the comparison of the two systems, the consequences of replacing LA with legal expenses insurance and its impacts on the litigation resolution mode are

identified. The arrangements accepted by plaintiffs covered by a legal expenses insurance policy appear to be higher than those demanded by plaintiffs benefiting from LA, irrespective of their risk aversion. Consequently, LA appears to be more favorable to arrangements than legal expenses insurance because it makes plaintiffs less demanding. The development of legal expenses insurance could therefore appear to be desirable for plaintiffs but not for the legislator wishing to reduce legal proceedings.

Summary

Legal aid has seldom been explored by the economic literature. The studies – mainly European – provide interesting results regarding the avoidance of conflicts, in terms of the incentives to prosecute, to come to an amicable settlement, and to take precautions. They also shed new light on the behavior of lawyers. These analyses may prove to be particularly useful with the prospect of reforms seeking to reduce the burden of LA in government budgets, perhaps by replacing it with other methods of financing access to justice (contingent/conditional fees or legal expenses insurance). However, empirical studies that confirm or invalidate the main theoretical results remain sorely lacking.

Legal Disputes

Richard E. Wagner
Department of Economics, George Mason
University, Fairfax, VA, USA

Abstract

In bringing economic analysis to bear on whether a dispute is settled without trial, the presumed institutional setting is typically one of private property where the parties are residual claimants to their legal expenses. Many disputes, however, are between private and public parties. In these disputes there is a conflict between substantive rationalities because public parties are not residual claimants. Just as

the substantive content of action can vary depending on whether the actor operates within a context of private or common property, so can the substance of dispute settlement vary. While a public actor cannot pocket legal expenses that are saved through settlement, the expenses of trial can serve as an investment in pursuing future political ambitions.

Definition

A sizeable literature exists on the resolution of legal disputes, which is summarized to good effect in Miceli (2005), and with that summary containing an extensive bibliography. That literature largely operates within the framework of a dispute between two market-based entities where both parties operate within the substantive rationality associated with private property. In many legal disputes, however, one party is a public entity which operates within the substantive rationality associated with collective or common property, as Wagner (2007) explains in his treatment of public squares and market squares. This entry explores how the economic principles of dispute resolution might be modified when one of the parties to a dispute is a public entity. To provide a point of analytical departure, I start with a quick summary of dispute resolution when both parties operate inside a framework of private property. The rest of the entry explores how the analysis of how the resolution of legal conflicts might be modified when one of the parties is a public entity. The entry closes by considering some of the constitutional-level issues that arise in light of the societal tectonics that can be generated in the presence of this clash between rationalities.

Dispute Resolution Between Private Parties

Someone who buys a dilapidated hotel hires a construction firm to renovate the hotel. The

contract calls for a series of payments corresponding to various stages of completion of the work. The construction firm hires workers and contracts for the delivery of materials. The renovation is projected to take 2 years. Shortly after renovation starts, the hotel's owner discovers a considerable miscalculation in the financial projection on which the renovation was based. Correcting the mistake, however, lowers significantly the expected value of renovation. Consequently, the hotel owner revises the planned renovation and offers the owner of the construction firm a new contract, one that calls for less work, a later starting date, and a lower price. The owner of the construction firm refuses to accept the lower price, saying that the revised work plan and the different materials involved, along with complications due to the later starting date, warrants payment of the original price. The hotel owner refuses and demands that renovation proceed under the new plan, so the construction firm sues the hotel for the \$20 million.

The logic of settlement looks at the situation from the point of view of each party and asks whether there are conditions under which both parties could gain by settling the case rather than going to trial. For the plaintiff, the object of a trial is to acquire the amount requested; for the defendant, the object is to avoid having to pay that amount. For a plaintiff, the expected gain from going to trial, P_T , is $P_T = AP_P - E_P$, where A is the amount requested, P_P is the probability of success expected by the plaintiff, and E_P is the plaintiff's expense in pursuing the trial. For a defendant, the similar relationship is $D_T = AP_D - E_D$. In this instance, $A = \$20$ million. Suppose for each party the expected cost of pursuing a trial is \$2 million. Further suppose that each party believes its chance of success at trial is 50%. Under these conditions, each party has the same net expected value from going to trial, \$8 million.

The aggregate net value of going to trial is \$16 million, but the award generated through the trial is \$20 million. The other \$4 million is dissipated through litigation. This dissipated amount illustrates the potential gain from settling the case. A settlement where the defendant paid the

plaintiff \$10 million would split the settlement range evenly, leaving each party with \$2 million more than they could expect to obtain through trial. Any payment to the plaintiff between \$8 and \$12 million would provide gains to both parties. The existence of a settlement range fits with the observation that most commercial disputes are settled without trial. But not all such disputes are settled, nor is there any reason to expect that they should all be settled. For instance, there is no necessary reason for both parties to have the same perception of the outcome of a trial. In dealing with expectations about particular events, there is no reason to think that the sum of probabilistic beliefs must add to one. Each party might be optimistic about the outcome of a trial, as illustrated by each party thinking that its chance of success was 80%. In this case, the expected value of going to trial would be \$14 million for each party. With trial now offering what the parties perceive to be an aggregate value of \$28 million when only \$20 million will be awarded, the settlement range vanishes amid the inconsistent perceptions. To be sure, there is good reason to think that such procedures as discovery and deposition operate to narrow the distance between perceptions; however, while the tendency to settle disputes is economically intelligible, settlement is not economically necessary.

What is particularly significant about this formulation is that both parties operate within a framework of private property where each entity owns the value consequences of its actions. The basis for settlement resides in the institutional framework of private property wherein the parties can pocket the legal expenses avoided by settling the dispute. This framework fits normal actions of private law involving disputes between two commercial entities. But a good number of disputes in modern societies are between private and collective entities. With collective entities, however, there is no ownership of the value consequences of collective action, at least within democratic regimes. To explore the resolution of such disputes, it is necessary to take into account differences in practical rationality between differently constituted entities.

Form, Substance, and Rationality in Practical Action

Economists typically work with a purely formal notion of rationality, as expressed by the axiom that people make consistent choices. This formal notion of rationality pays no attention to the context within which choices are made. It does this by presuming that all choices are made within a market context where people choose among options according to market prices. This context, however, applies only to a subset of all choices and interactions within a society. Political choices, for instance, are not made within this context even though public choice theorizing tended to assume that they are doubtlessly to increase analytical tractability.

With respect to the preceding example, suppose the plaintiff is not a construction firm but an environmental control agency that is seeking to force the hotel owner to change the renovation in a manner that adds \$20 million to the expenses of renovation while adding nothing of potential value to future customers. The hotel owner can sue the environmental agency. The market-based settlement calculus, however, does not apply in this context. It applies to the hotel owner, of course, but it does not apply to the environmental agency because the agency operates outside the purview of private property and residual claimancy. The agency still engages in economic calculation because it always faces choices, but the context of calculation differs through the absence of residual claimancy, which means, among other things, that there is no market valuation of the environmental agency that some owner can claim directly.

There is a formal logic of choice, and there are substantive logics of practical action, as noted cogently by Pierre Bourdieu (1990, 1998). As a formal matter, it is reasonable to presume that people prefer more of what they value over less. As a substantive matter, however, what is valued depends on the context within which action is taken. Among athletes, for instance, practice will be the form by which the athlete prepares for competition. The substance of that practice, however, will depend on the context of competition.

For someone engaged in American-style football, weight lifting will be a significant component of practice. In contrast, someone engaged in billiards might not lift weights at all. There are many substantive logics of practice that can all be rendered sensible within a covering logic of form, as illustrated by Alasdair MacIntyre's (1988) distinction between a rationality of excellence and a rationality of effectiveness.

The logic of practice must relate cost to choice along the lines Buchanan (1969) sketches. Cost is thus the value an actor places on the option that is displaced by virtue of choosing the alternative. The cost of choosing to settle a case is the value of the option that the chooser foregoes by choosing instead to go to trial. The relevant cost, however, pertains to a person who faces a choice, and that cost differs between frameworks of private property and collective property, as Ringa Raudla (2010) notes in her treatment of incorporating institutional considerations into the theory of public finance. For instance, someone who fishes on a private pond will tend to return immature fish to catch later, while someone who fishes on a common pond cannot count on those fish still being there later when they are larger.

With respect to commercial disputants, it is reasonable to relate cost to perceptions of the comparative value of an enterprise in light of the options. With respect to the value of the enterprise in the preceding illustration when both parties agree on the 50-50 assessment of prospects of a trial, the value of the enterprise is \$2 million higher with settlement than with trial. That value, moreover, accrues to the owner of the enterprise. While in a large firm it will be the director of a legal office that makes such decisions, that director will bear a clear agency relationship with the owner of the firm. With collective entities, however, at least of the democratic form, there is no market for ownership, and so there is no value of the enterprise. It is still possible as a formal matter to treat collective entities as enterprises, but there is no market-based valuation of those enterprises. The relevant cost to the director of an environmental agency is not reflected in some calculation of enterprise value because there is no such value.

For such an agency, choices to settle or go to trial must be related not to some fictional construction of firm value but to the cost-gain calculus faced by the director of the agency, as modified by other political interests that the director values highly. There is still a formal logic of settlement, but the specific decisions regarding settlement are guided by the substantive logic of practice within a particular institutional framework. To get at substance requires that choices be related the chooser's valuation of perceived options at the level of practical action. Both football players and billiard players will practice for forthcoming competitions, but the substance of their practices will differ. In similar fashion, someone who fishes on a common fishing ground will act differently than someone who fishes on a privately owned pond.

Dispute Resolution Within a Mixed Economy

In her perceptive treatment of *Systems of Survival*, Jane Jacobs (1992) explained that well-working societies operate with a delicate balance between what she described as commercial and guardian moral syndromes. While her distinction wasn't identical to the distinction between commerce and government, it was close. She also explained that when the carriers of those syndromes commingle excessively, what she termed "monstrous moral hybrids" can arise. Such commingling comprises what is described as a mixed economy (Littlechild 1978; Ikeda 1997). The central issue that such commingling must confront is whether it supports or revises the character of the economic order. While democratic systems are based on a logic of equality and mutuality, there are plenty of analytical grounds for recognizing that they also face pressures leading toward a re-feudalization of the economy. It was to forestall such re-feudalization that Walter Eucken (1952) articulated the principle that state action should be market conformable. Such market conformability in Eucken's framework would present a barrier to the generation of monstrous moral hybrids in Jacobs's framework.

When both parties to a dispute operate within a private property framework, they both speak the same language of profit and loss. For instance, the defendant might be the hotel owner after renovation, and the plaintiff might be the owner of an adjacent marina who complains that the height of the hotel blocks a view of the setting sun, thereby degrading the value of the rooftop restaurant. Both participants speak the language of profit and loss. While each would have understandable incentives to exaggerate their cases, that exaggeration is limited by their positions of residual claimants and the possibility that settlement might lead to higher net worth than trial.

The setting changes if the plaintiff is an environmental agency or any political entity for that matter. The hotel still speaks the language of profit and loss, but the environmental agency speaks a different dialect, one that refers to social value that cannot materialize in anyone's account in particular. What results instead are ideological appeals that resonate with targeted interest groups along the lines of Pareto's (1935) treatment of ideology as amplified by Backhaus (1978) and as explored further in McLure (2007). In Pareto's terms, we observe the agency filing suit against the hotel, and we witness the agency advancing derivations or justifications based on claims of capturing social value. What we don't know about are the underlying motivations that led to the agency choosing that course of action, which Pareto called residues. The agency cannot claim to be trying to capture lost profits, and in this it is speaking truthfully because there are no profits that it can capture due to its status as a nonprofit entity. But in speaking of securing the social interest, it is advancing a proposition that is incapable of falsification. The head of the agency might well aspire to run for public office and sees this suit as a means of capturing favorable publicity. If so, the suit offers the head of the agency an investment at public expense in achieving that electoral outcome, though, of course, no person with such electoral aspirations would ever make such a declaration. In a suit between market participants, both parties can be honest and open in their aspirations. But when one party is a public entity, such rectitude necessarily and understandably recedes.

Disputes involving both private and public parties entail a form of Faustian bargain. Public parties can sue private parties without having to face the constraints upon the power to sue that private property imposes on market participants. In some instances, reasonable public purposes might be secured by the deployment of that power. But that power can also be employed in the pursuit of the private advantages of those who wield that power, as perhaps illustrated by an attorney general who is able to parlay legal expenditures into investments in an effort to seek higher elected office.

It is doubtful that there is any resolution to this particular Faustian bargain. This form of bargain bears a family resemblance to the problem of statistical decision theory as illustrated by Jerzy Neyman's (1950) treatment of the problem of the lady tasting tea. In that problem, a lady claims to be able to tell whether milk is added to tea that is already in the cup or whether tea is added to milk. It is in the nature of the problem setting that perfection is impossible. The greater the effort made to avoid granting the lady's claim when she really can't distinguish between the methods, the greater will be the frequency with which her claim will be rejected even though she can distinguish between the methods.

This problem setting has relevance for constitution of dispute resolution within society. Along the lines of Epstein (1985), a public agency might take private property under eminent domain, claiming that it had good public reason for doing so. After all, what else could it claim? The Fifth Amendment to the US Constitution requires that such takings be only for public purposes and that any such taking must be accompanied by just compensation. It is easy enough to give a Coasian gloss on this procedure. The ability of the hotel to build upward might destroy scenic opportunities elsewhere that are valued more highly than what is created by adding to the height of the hotel. There is a simple market test for this proposition. But in the absence of a market test, the burden falls on the public processes through which agency actions are determined. Some of those processes might be more market conformable than other processes. In any case, relationships between market-based and public-based entities create a source of turbulence that is

not present in relationships between market-based entities, due to differences in the substance of rational action.

Legal Formants

Bianca Gardella Tedeschi
DiSEI, Dipartimento per lo Studio dell'Economia e dell'Impresa, Università del Piemonte Orientale, Novara, Italy

Definition

Legal formants are the different components that concur to build any given legal system. The

comparative law scholar can understand the dynamics that shape any legal system through the analysis of their interactions. Legal formants analysis of legal systems have been developed by Rodolfo Sacco, and it is now a recognized and accepted methodology by comparative law scholars.

A Dynamic Approach to Comparative Law

Legal formants are the different components that concur to build any given legal system. The comparative law scholar can understand the dynamics that shape any legal system through the analysis of their interactions. The expression “legal formants” have been transplanted in comparative law from phonetics by Rodolfo Sacco, an Italian law professor based in Torino. “Legal formants” made their appearance in Sacco’s work since the early 1970s (Sacco 1974) and have been subsequently included in his seminal book on comparative law (Sacco 1980). Legal formants theory have been available to the English reader in 1991 (Sacco 1991a, b).

Comparative law is the academic subject that identifies the “plurality of rules and institutions . . . in order to establish to what extent they are identical or different” (Sacco 1991a: 5). To achieve this intellectual exercise, comparative law scholars have to collect legal rules, in order to be able to analyze and compare them. Sacco’s theory rests on the question “what is a legal rule?”, as the comparative law scholar has to extract the lesser object of his study from the wholeness of the legal system. From a national point of view, the answer to question, “what is a legal rule” may be simple: national jurist in civil law jurisdictions is willing to say that the legal rule is what a statute says, whereas in common law countries would be what case law affirms. Sacco, however, considers wrong to search for “the legal rule” on a specific subject. This attitude is, in his words, “the typical view of an inexperienced jurist” (Sacco 1991a: 21). In fact, any trained lawyer, “who proceeds from the axiom that there can be only one legal rule in force, recognizes, even only implicitly, that the living law contains many different elements:

statutory rules, the formulations of scholars, and the decisions of judges” (Sacco 1991a: 22). The national jurist tends to keep separate all these elements in the back of his mind. But still: “The statutes are not the entire law. The definitions of legal doctrinal scholars are not the entire law. Neither is an exhaustive list of all the reasons given for the decisions made by the courts. In order to see the entire law, it is necessary to find a suitable place for statute, definition, reason, holding and so forth. More precisely, it is necessary to recognize all ‘legal formants’ of the system and to identify the scope proper to each” (Sacco 1991a: 29).

“The number of legal formants and their comparative importance varies enormously from one system to another. For example, in some areas of English law, statutes are wholly lacking” (Sacco 1991a: 32). So, what can constitute a legal formant? Constitutions, statutes, case law, and scholarship are legal formants. They are so as texts, as well as work of legal actors, for they include the social practices of each particular group of interpreters. Even the way law is explained to law students in the classroom is a legal formant as teaching concurs to the modelling of the legal system. Interpretation is itself a legal formant: “Whatever influences interpretation is a source of law. To discover what influences interpretation various methods can be used. For example, one can examine the sources that an interpreter uses, be he lawyer or judge, when he advocates or adopts an interpretation of a rule” (Sacco 1991b: 345).

In Sacco’s understanding, “the reasons and the conclusions given by judges and scholars” (1991a: 30) are also legal formants. “Strange as it may sound, the reasons that judges and scholars give are different “legal formants” than their conclusions. The reasons have a life of their own, independent from the conclusions they supposedly support” (Sacco 1991a: 30).

“The propositions about the law that are put forward as conclusions by scholars, legislators, or judges are another legal formant” (Sacco 1991a: 31).

Reasons and propositions about the law are what Sacco considers “declamatory statements,” whereas “operational rule” designates the legal

rule, as it is applied. Sometimes “declaratory statements . . . make explicit an ideology, be it the ideology that actually inspire[s] the system in question or the one that a given authority believes to have inspired it or the one this authority wishes people to think inspired it. In civil law and in common law countries, declaratory statements are often made in accordance with the background of *jus naturalism*. Declaratory statements, for example, may insist that contracts are made by consent, while the operational rule requires not only consent but a reason or cause for the enforcement of the contract. . . Or, in common law countries, there are declaratory statements that property is transferred by the will of the parties while the operational rules require an additional element: consideration or delivery or, for the transfer of immovable property, a conveyance” (Sacco 1991a: 31).

National jurists assume that all legal formants in the same legal system have an identical content, that’s why the task for the national jurist is the quest for “the legal rule” within the system. Sacco’s theory, however, shows that the legal formants, within a given legal system, are never in complete harmony. “Comparison recognizes that the “legal formants” within a system are not always uniform and therefore contradiction is possible. The principle of non-contradiction, the fetish of municipal lawyers, loses all value in an historical perspective, and the comparative perspective is historical par excellence. Despite the search of unity and certainty of law, the comparative law scholar is able to show that the different legal formants are not in harmony, but rather in conflict” (Sacco 1991a: 24). An example comes from the interpretation of code provisions that are adopted with identical wording in two different legal systems. It may happen that, despite the exact wording of the statutory provisions, the two judges interpret the provisions in different ways and therefore apply different rules: the statutes alone do not determine the rules followed by the judges.

The dynamic approach, through the analysis of multiple legal formants, is opposed to the static approach based on dogmatic. The static analysis of a legal system looks for the “the rule” that must exist and, if not evident, can be deduced logically

from the official sources of law. The dynamic approach allows the observer to understand the whole picture, to take into account the different forces that are at work in shaping legal systems and to acknowledge the work that all the legal actors provide. The dynamic approach focuses on law as a social activity and refutes those “scientific” methods of legal reasoning that do not measure themselves against practice, but formulate definitions that are supported solely by their consistency with other definitions” (Sacco 1991a: 25).

The dynamic approach is at odds with positivism. A dynamic approach enables the observer to distinguish between the description that the legal system offers of itself (declaratory rule) and the rule that is in fact enforced (operative rule). A system, for instance, may grapple around the declaratory rule that affirms total and absolute “privity of contract” and then, in specific circumstances, allows compensation for interference with contract. If the set of facts that allows compensation are recurrent, we have an operative rule that is different from the declaratory rule: in specific circumstances, the contract is relevant for third parties that are obliged to pay damages in case of interference.

Sacco’s approach to law through legal formants is deemed a structuralist approach, as structuralism, in law, debunks the myth of the legal rule (Mattei 2001). Structuralism, as well as Sacco’s dynamic approach to comparative law, “show [s] that each rule is a complex structure composed of different “formants”: the rule formulated by the legislature, the rule as interpreted by courts, the implementation of the rule by administrative agencies, the discussion of the rule by law professors, etc. It also makes plain that each rule consists of both an operative prescription and a justification for that prescription, thereby emphasizing the role played by ideology and rhetoric” (Di Robilant 2016: 1326–1327).

Tacit, or Implicit, Legal Formant: The Cryptotype

Beside explicit legal formants, such as statutes, case law and scholarship, there are implicit legal

formants that Sacco calls “cryptotypes.” The terminology is imported from linguistics (Legrand 1995: 953–955). When we speak, very few of us would be able to formulate the linguistic rule we follow when we say “three dark suits” and not “three suits dark.” According to Sacco, the same applies to law. It happens that jurists follow and apply rules not explicitly formulated or enforce rules they are not aware of. In our experience, the law has become a theoretical exercise, especially since we have, within the society, a particular class of professional jurists. But even in our times, social order and performance are always extant in the shaping of rules and legal systems and they always keep a different and practical dimension. Customs, the social practices, and rules of conduct that people follow within social groups, that ultimately guide the actions of the members of a community, are what Sacco defines as “cryptotypes.” Judges, lawyers, interpreters are equally bound to the implicit formants that, therefore, are very influential in the modelling of different legal systems.

It is not easy to identify cryptotypes. It is even harder for national jurists, as they involuntarily follow rules they are unaware of. “Normally, a jurist who belongs to a given system finds greater difficulty in freeing himself from the cryptotypes of his system” (Sacco 1991b: 387). This is why comparative lawyer is privileged in detecting cryptotypes, as she is an outsider who doesn’t share the same implicit rules. “Some cryptotypes are more specific, others more general. The more general they are, the harder they are to identify. In extreme cases they may form the conceptual framework for the whole system” (Sacco 1991b: 386).

Legal Formants and Factual Approach: The Common Core Project

The Legal formants approach to comparative law is part of the methodology applied by the large group of scholars that participate in the Common Core Project. The Project, established in Trento in 1993, by Ugo Mattei and Mauro Bussani, aims at “unearth the common core of the bulk of

European Private Law, that is, of what is already common, if anything, among the different legal systems of European Union Member States” (Bussani and Mattei 2002: 1). Two methodologies were drawn together by Bussani and Mattei for the Common Core Project: the factual approach to comparative law, conceived by Rudolf Schlesinger (Schlesinger 1968) and the dynamic approach to comparative law, elaborated by Sacco (Mattei 2001).

The first source of inspiration has been the Cornell seminars held by Rudolph Schlesinger in the 1960s. Schlesinger’s endeavor was to describe how the rules on formation of contracts were functioning in various legal systems (Sacco 1991a: 29–30). Instead of asking participants to describe their own legal systems, he preferred to draw a questionnaire based on specific-case scenarios. His project launched what is now known in comparative law as the “factual approach.” Schlesinger’s work provides an accurate comparative overview, because an inquiry on how different legal systems solve the same practical problems better describes the functioning of a legal system. This approach is known by now as a functional approach, meaning that legal rules are best described by their function (Graziadei 2003).

Together with the factual approach, Common Core Project was inspired by Sacco’s theory on legal formants. This theory allowed national reporters as well as editors in charge of drawing the final comparative overview to have the full picture of the dynamic that do operate within a given legal system. In the instructions given to participants about how to answer the questionnaires (Bussani and Mattei 2002: Annex transform in 1), we read: “On a first level (‘operative rules’), the national reporters are asked to indicate how the case would be solved according to case law, legislation, legal doctrine, custom and usage” (Hesselink and Cartwright, 3). They should indicate as well “whether these formants are concordant. . . from an internal point of view and from a diachronic point of view. On a second level (‘descriptive formants’), the reporter is to indicate the reasons why lawyers feel obliged to adopt the solutions described at the first of the inquiry. Finally, on a third level (‘metalegal formant’, or

cryptotypes), the reporters are invited to indicate any other element that might affect the solutions mentioned at level 1, such as policy considerations, economic factors, social context and values, and the structure of legal process” (Hesselink and Cartwright 2002: 3; cf. Cartwright and Hesselink 2002 for a description and critiques of Common Core Project).

Legal Formants in Critical Legal Theory

Critical legal thought praised the legal formants approach to the analysis of law. Duncan Kennedy in a Critique of Adjudication (1997: 92) states the importance of Sacco’s approach, as a formidable tool in the scholars’ hands. Legal formants, showing the dynamics within a legal system, refute the idea of the inevitability of deduction. “A comparative method can thus provide a check on the claim of jurists within a legal system that their method rests purely on logic and deduction” (Sacco 1991a: 24). There is no obliged logical deduction from a legal rule. Duncan Kennedy bases his praise for Sacco’s work on the description of how identical code provisions are applied differently. For Kennedy, this is the evidence of the possibility for the judge, the scholar, and more broader the interpreter, to choose among various possible application of the rule. The judge, the scholar, and the interpreter cannot hide behind the neutrality of the law, neither behind the logic of the law. Any application of the rule, within any legal system, is a specific choice for the interpreter. Legal formants, therefore, are extremely effective in conducting an internal critique, to debunk the neutrality of the legal system using the same devices that the various legal actors use.

At the same time, Duncan Kennedy (2012) urges the comparative law scholar to take into account ideology as a legal formant that operates in an implicit way, therefore a cryptotype. The mainstream comparative law has not been particularly focused in this direction. According to Kennedy, if the deductive process of the judge, the scholar, and the jurists community is not determined, constrained, or forced by legal necessity, it is clear that the community of the interpreters

are actually choosing the solution. How do they determine the rule that they are going to apply is the central question of Duncan Kennedy’s scholarship. Confronted with legal formants methodology, he is willing to unveil ideology (Du. Kennedy 1997: 157–179) as one of the components of legal systems, that implicitly influences decisions. Ideology is therefore one of the most effective examples of cryptotypes, because it influences jurists’ decisions in an unconscious way. Classic comparative law, though, never considered politics and ideology as part of the legal system, because classic comparative lawyers preferred to situate themselves on a scientific level, where law is a technical and autonomous subject that has a separate life from politics.

Comparative Law and Economics

In the 1990s, Ugo Mattei, a comparative law scholar who studied law and economics in the United States, proposed a new approach to legal research (Mattei 1997; cfr. Mattei and Cafaggi 1998; Caterina 2006). Comparative law and economics was “the new frontier” (Mattei and Cafaggi 1998: 346) of legal scholarship that could “enable scholars to tackle major challenges of globalization” (Mattei and Cafaggi 1998: 346). Comparative law, the science that addresses the study of “similarities and differences between legal systems, is conjugated with law and economics,” (Mattei and Cafaggi 1998: 346) the science that evaluates legal rules and institutions from the point of view of economic efficiency. The final goal of this new academic challenge was to assess which legal system was more efficient. “Comparative law and economics seeks to explain in precise terms the convergence of legal rules by using efficiency as a key metric” (Di Robilant 2016: 1387). The legal formants approach is paramount in this endeavor, as it takes into account all the forces at work in a legal system, and not only black letter law. In addition, a dynamic approach sheds light on how and in which measure the rules and the community of jurists are actually working, consciously or

unconsciously, to build a more efficient legal system.

Comparative law and economics, in the hope of the founder, could work both at the level of positive and normative analysis. At the positive level, comparative law and economics can provide useful insights for understanding the reasons of the differences and the peculiarities of each legal system vis à vis the more universalistic efficient model. At a normative level, the scholar can suggest policy changes that move any legal system towards efficiency every time that a distance from the universalistic model is not justified. Moreover, comparative law and economics could give important contributions to the pattern of legal change, especially through the analysis of competing legal models and their inclusion in the legal system through the various legal formants, including path dependency and implicit legal formants (cryptotypes). It is well known that in the globalized world, legal systems are subject to changes, sometimes imposed, sometimes voluntary. Comparative law and economics can provide an understanding on which legal formant takes the responsibility for the change.

The development of comparative law and economics proceeds at slow pace in the academic legal analysis for several factors. Ramello (Eisenberg and Ramello 2016a: 3) identifies the causes in the lack of a specific journal that gives “dignity” to the discipline, and in the European character of comparative law and economics, uninteresting to the USA, and therefore global, scientific environment. This said, we can add that very few scholars are equipped for the task: it requires a good preparation in both disciplines, both comparative law and economics, usually very distant one from the other; secondly, the methodology is not always clear, same for expected results. Ramello and Eisenberg are willing to revive this particular angle of the discipline, bringing more comparison and a more cross-boundaries viewpoint into law and economics. Their recent book (Eisenberg and Ramello) is definitely heading towards this direction.

It is still unclear if legal originalists approach to legal systems, that led the way to World Bank

“Doing Business” reports, falls into the broader category of “comparative law and economics” (Eisenberg and Ramello 2016b: 8–9; Michaels 2009b). Through this program, the World Bank established its own method of assessing economic efficiency of legal systems (Djankov 2016; Michaels 2009a, b). The reports provide “objective measures of business regulations and their enforcement across 190 economies” <https://nation.com.pk/29-Jan-2018/conducive-environment-for-business>.

The reports “gather and analyz[e] comprehensive quantitative data to compare business regulation environments across economies and over time” <https://nation.com.pk/29-Jan-2018/conducive-environment-for-business>.

The “Doing Business” reports “encourage economies to compete towards more efficient regulations; they offer measurable benchmarks for reform and serve as a resource for academics, journalists, private sector researchers and others interested in the business climate of each economy” <https://nation.com.pk/29-Jan-2018/conducive-environment-for-business>.

Legal Insurance

► Litigation and Legal Expenses Insurance

Legal Origin

Maria T. Brouwer
Amsterdam, The Netherlands

Abstract

Flexible common law is considered to be more conducive to external investment than more rigid civil law. However, both systems can either adapt to new situations or become less flexible over time. Legal systems function best, when there is sufficient room for revision and review.

Definition

The concept of legal origin stems from the law and economics literature. It analyzes the effects of different legal traditions on economic performance. Common and civil law systems have spread over the globe and impacted the organization of economic life in Western Europe and former colonies.

Law Systems

Common law is of English origin and prevails in the UK and former British colonies. Judges have a great degree of discretion in common law systems. Common law evolves gradually through decisions in specific disputes that are upheld by higher courts. It differs from civil law that depends on legal statutes and comprehensive codes. The legislator in civil law systems wants to provide rules for as many situations as possible. Judges can only use discretion, if the legislator either overlooked the problem or left it deliberately open for the courts (Buetter 2002, 29). History has shaped how courts take decisions. French

judges became bureaucrats employed by the state, while English judges gained considerable independence from the Crown in the Glorious Revolution of 1688 (Mahoney 2001). Common law is said to support market outcomes, while civil law takes directions from the state. Civil law codes originate in the French Code Napoleon of 1804. The Code Napoleon abolished feudal rights and offered equality under the law to everybody (but not to married women). The Napoleonic Code was imposed on conquered territories in Italy, Spain, the Rhineland, and the Low Countries. Many of these countries voluntarily adopted the Napoleonic Code after Napoleon's defeat. The Dutch Civil Code of 1838 and the German Civil Law of 1898 are offshoots of the Code Napoleon (Meijer and Meijer 2002). The German Civil Code differs somewhat from French civil law and constitutes a different class. Scandinavian law differs and constitutes a class of its own. Legal origin theory, therefore, divides countries in four groups: (1) common law countries, (2) French civil law countries, (3) German civil law countries, and (4) Scandinavian civil law countries. Former colonies adopted the legal code of their former rulers after gaining independence.

Legal Origin and Financial Development

The law and finance literature found that financial development is related to legal origin. Common law countries make more extensive use of external finance (LaPorta et al. 1998). Both shareholders and creditors are better protected in common than in French civil law countries. Cross-country research found that French civil law countries have smaller stock markets, less active public offering markets, and lower levels of bank credit as a percentage of GDP than common law countries (LaPorta et al. 1997). A predominance of debt over equity finance characterizes civil law countries. This applies with the greatest force to Germany and Japan (LaPorta et al. 1997). Debt finance is ill suited to cope with entry and exit of firms. Both Europe and Asia showed little turbulence in their populations of quoted firms due to the scarcity of new quotations. This differed from the USA, where new firms appeared in droves on

the NYSE and Nasdaq after 1980. Failing firms in German civil law countries could cause the collapse of lending banks. A greater reliance on equity in common law systems offers more opportunities for continuation in bankruptcy proceedings. More US bankruptcies resulted in reorganization and continuation than in continental Europe (Brouwer 2006). The distinction between civil and common law countries overlaps that between relationship and market-based financial systems (Rajan and Zingales 1998). Anglo-Saxon countries have market-based systems, while continental Europe and Asia feature relationship-based systems. Rajan and Zingales found that market-based systems grow faster. Anglo-Saxon finance is more hospitable to entrant firms and therefore better suited to finance innovation (Djankov et al. 2002). Relationship banking, by contrast, mainly funds tangible assets that can be used as collateral to loans. The higher risk associated with debt finance prompts financial intermediaries in continental Europe and Japan to bet on the same risks. All are rescued by the state, if disaster strikes (Rajan and Zingales 2003, 18).

Legal Origin and Economic Development

Common law seems better suited to further economic development than civil law. Former English colonies like the USA, Canada, and Australia illustrate this narrative. However, not all former English colonies in Africa and Asia show superior economic performance. Japan that adopted German law outstripped economic growth in many former English colonies. Moreover, Belgium, France, and Germany achieved rapid economic growth after 1945. The empirical evidence is, therefore, not completely in favor of common law countries. Common law countries grew more rapidly in the 1960–2000 period than French civil law countries. German civil law countries, however, grew fastest (LaPorta et al. 2008). High costs of litigation and judicial arbitrariness are mentioned as reasons for slow growth in common law countries. The relative good performance of France, Belgium, and the Netherlands is ascribed to the more flexible use

of French civil law by judges in those countries. Judges in Italy and former French colonies stuck more to the letter of the code (LaPorta et al. 2008). Jurisprudence was recognized as a source of law in German courts, which enhanced flexibility. The capacity of legal codes to adapt themselves to new circumstances might, therefore, be more significant in explaining economic development than origins. Common law systems are said to evolve toward efficient rules through sequential decisions by appellate courts that can reverse decisions. The trial and error character of common law systems promotes flexibility. Napoleon did not allow for judicial review by judges. The centralized judiciary he installed was deemed superior to the arbitrariness of local judges of the ancien regime. French judges were villains in constitutional development, while English judges were heroes (Mahoney 2001). The English king was not above the law in contrast to French civil law. But, France installed administrative courts to review rules and decisions made by the state.

The Debate

The legal origins hypotheses put forward by LaPorta et al. have sparked an intense debate between proponents and critics. Critics pointed at the good economic performance of civil law countries like Japan, Belgium, and Germany. Culture, politics, and history were more important than legal origin in their view (LaPorta et al. 2008). Intermittent variables instead of legal origin might explain the differences between the different law systems. Years of schooling are sharply higher in common law than in French legal origin countries. Some authors point to religion to explain differences between countries. Protestant England was more conducive to market-led growth than Catholic France. Politics are also mentioned as explanation for divergent economic performances. Social democracy took root in continental Europe but is absent in the US-A. Others point at the reversibility of financial markets over time. Latin American countries of French legal origin were more financially developed than the USA and the UK in 1913 (Rajan and Zingales 2003). LaPorta et al. refute these critiques in an

elaborate response. They argue that the distinction between French civil and common law elucidates a host of phenomena from financial development, to regulation and state ownership of banks and companies. The beneficial effects of common law systems derive from the smaller hand of the state in economic affairs than in civil law countries. Heavy government interference entails more corruption, a larger unofficial economy and higher unemployment (LaPorta et al. 2008).

Anglo-Saxon Finance Came to Europe

Common law countries leave more to markets, while civil law countries turn to the state to solve economic problems. However, recent developments have put several characteristics of common law countries into question. The spread of Anglo-Saxon finance over the globe in the past decades has largely eliminated the differences in financial development among western European countries. Bank loans to the private sector as a percentage of GDP in continental Europe were almost equal to that of the USA in 2000. Stock market capitalization of continental European countries increased sharply from 17% in 1980 till 60% of US and UK capitalization in 2000 (Rajan and Zingales 2003). However, financial catching up did not boost entrepreneurship in continental Europe. There were few technological start-ups in Europe due to a lack of early stage venture capital. However, Europe became familiar with Anglo-Saxon private equity and hedge funds. These vocal shareholders demanded changes in executive boards and the breakup of companies. Many corporations were acquired by private equity or were prompted by hedge funds to sell themselves out to increase shareholder value (Brouwer 2008, Chap. 7). Globalization of finance might spell the end of relationship banking and the spread of market-based transactions. But, it is questionable, whether this financial convergence will stimulate economic growth. Anglo-Saxon financial innovations were a main cause of the financial crisis of 2008/2009 that led to the near meltdown of the world financial system. Securities based on mortgages lost most of their value, when home prices dropped and foreclosures abounded. The US securities were sold to

domestic and foreign banks, whose balance sheets deteriorated, when the losses appeared. Banks tended to collapse, when trust evaporated and interbank lending came to a halt. States had to step in to prevent banks from failing in both the USA and Europe. Financial markets are only stable if investor opinions on projects and people differ. No securities would change hands if investors would all agree on the value of a security (Brouwer 2012, Chap. 4). Security prices take a dive when investors are all looking for the exit and boom when investors enter financial markets in herds. Superior performance of Anglo-Saxon finance rests on independent, uncorrelated investor decision-making. But, investors came to rely heavily on opinions of rating agencies. Herd-like behavior caused a worldwide financial crisis. Banks participated in derivatives trade that did not create value but distributed gains and losses among buyers and sellers of these securities. Moral hazard problems appeared, when losing banks needed to be rescued by central banks. Both financial markets and legal courts are methods to solve disputes and differences of opinion. Judges take decisions after hearing both parties. Markets bridge the difference between buyer and seller valuations of a security. Security prices change continuously on secondary markets reflecting changes of investor opinion. Court decisions can be reversed on appeal or review. Landmark decisions by higher courts confirm new interpretations of the law. Financial markets and courts stir development, if initial differences of opinion are resolved through discourse.

Conclusions

The relationship between legal tradition and economic performance is not time and place invariant but depends on the quality of discourse and decision-making in markets and judiciaries. Both common and civil law systems can function well, if they allow dissent and overcome differences of opinion through appeal procedures and judicial review. Common law systems are more conducive to discussion, but discourse stops if unanimous opinion prevails.

Legal Positivism and Law and Economics

Régis Lanneau

Law School, CRDP, Université de Paris Nanterre, Nanterre, France

Abstract

Law and economics scholars are rarely addressing traditional legal theory. Nevertheless, legal theory could help to better assess the limits of law and economics and the limits of legal theory. Moreover, legal

positivism largely paved the way for the emergence of law and economics. This entry will stress the points of convergence and the complementarities between these two approaches.

Introduction

Law and economics scholars are rarely addressing traditional legal theory and are often ignorant about legal positivism (with some exception of course, like Richard Posner (2003) or Lewis Kornhauser (2006, 2010) and Krecké (2016)). Legal theorists are frequently considering law and economics as an exteriority with its relevance often dubious for their own work; being “impure” (in a Kelsenian meaning of the word), it is not considered as “legal” knowledge. From this point of view, it is possible to consider that the legal positivism legacy could explain the transatlantic divide in the reception of law and economics (even if through a deeper analysis, this reality is not a necessity, Lanneau (2016)) and why law and economics remains controversial in the European legal academia. Despite this apparent mutual ignorance, both approaches are deriving from the same concern and appear complementary at many levels. Reciprocally legal positivism could enrich traditional law and economics. Being in an encyclopedia of law and economics, this entry will focus mainly on the former enrichment.

Legal positivism is hard to define precisely, and some could say that there are as many positivismisms as positivists. First, because the definition would change depending on the way it is conceptualized: legal positivism is different if it is considered as a methodology (a way to inquire into legal phenomena using the methods of natural sciences), as a theory of law (an inquiry into an object called “law”), or as an ideology (the primacy of positive law over all other normative systems). Second, because in each of these apprehension different schools exist: normativism, analytical school, post-positivism (for more details, see Grzegorczyk et al. 1993). Despite all these differences, it is possible to consider that positivists agree on three main theses. First, they

consider that law is the product of human beings; it is not something immanent. For that reason, law is perceived as an instrument. Second, and except when positivism is approached as an ideology, it is trying to develop a scientific approach of law derived from the methods of natural sciences and thus rejecting the classical distinction between episteme and praxis. Third, they are emphasizing the distinction between what is and what ought to be considering that the proper function of a science of law is to inquire into the is, not the ought (the ought would then define doctrinal approaches).

Before analyzing some of the points of divergence which are also explaining the complementarity between the two approaches (and its possible fertility), it is required to highlight the points of convergence to stress the common grounds of these approaches.

Points of Convergence

Legal positivism and law and economics are sharing two important features despite an under-theorization of law and economics. First, at the methodological level, both approaches are trying to develop a scientific approach to law. Second, at a value level, both are rejecting an immanent conception of law through a clear separation of law and morals.

Developing a Scientific Approach to Law

In order to develop a scientific approach of law, it is first required to distinguish between two levels of discourse: the level of the object (the law) and the meta level of the science (the science of law). The purpose of the science is then to describe its object (“what and how the law is, not how it ought to be” (Kelsen 1967). For that, it is required to follow a “scientific method,” a method based on causes and consequences since most legal positivists are fascinated by the methods of natural and empirical sciences. Thus, it is rejecting propositions which cannot be said either true or false (ideally on empirical grounds), it is rejecting the idea that there is an essence of things (since this essence cannot be the subject of scientific testing),

it is rejecting all forms of reason that are not episteme, and it is clearly distinguishing between the object and the science regarding this object. For Kelsen, a true science of law should “eliminate from the object of this description everything that is not strictly law” (Kelsen 1967). Of course, this approach is more aspirational than practical.

For law and economics, law is also an object of inquiry and economics (as a methodology to approach this object) is supposed to lead to some positive knowledge. This knowledge is not about the law considered as an object (what is the law?) but of the law considered only through its function (what are the consequences of the law?). This positive knowledge could be considered in two different ways. First, since the proposition about law are derived from models, the knowledge is positive (as logically derived from hypotheses); if we are assuming that people are rational and that law is providing constraints, then some consequences could be expected. Second, law and economics is more and more trying to empirically test some of its propositions to identify an “objective” effect of some law.

The Separation of Law and Morals

The separability thesis (the separation of law and morals) does not say that there are no links between law and morals or that we should not draw any lines between them. Indeed, Hart remarked that “There are many different types of relation between law and morals,” but “there is nothing which can profitably be singled out for study as the relation between them” (Hart 1983; 1994, 185). There are no essential (Hart 1958, 601) or necessary connection between law and morals; law is not dependent on morality. Because of this feature, law is, for a positivist, not defined by its content but by its structure (a set of primary and secondary rules for Hart, a dynamical system of Kelsen).

This content-free conceptualization of law is obvious in law and economics. Indeed, since the law is merely a function, it does not have any required content. Moreover, abiding by a consequentialist approach of ethics (since economics is consequentialist) it is prone to criticize any deontological conception regarding law and regulation

(Kaplow and Shavell 2002). This separation is also obvious considering that most scholars are enjoying debunking the inefficiency of morality tendencies in positive regulations.

Points of Divergence and the Complementarity of Approaches

For legal positivist, law and economics is lacking a clear concept of law. For law and economics practitioners, legal positivists are unable to address the consequences of norms or to rationalize the content of norms. Both of these blind spots – which could easily be explained by the focus of each approach – should be considered when addressing the value of each approach which appear from a practical point of view as complementary.

The Problem of “Validity,” the Blind Spot of Law and Economics

Despite the fact that for one of the major proponents of law and economics the question of what is law “has little practical significance if, indeed, it is a meaningful question at all” (Posner 1987, 765), having a concept of law is essential for at least two reasons. First, in order to have a clear understanding of what law and economics is, it is crucial to define what the law is for law and economics – otherwise the risk is simply equating an economic analysis of law to an economic analysis of norms; which is too often the case because the concept of legality is out of the reach of economic analysis (Lanneau 2010). Second, if the specificities of the law are not taken into account by law and economics, its value rests on poor foundations. Besides, to state that the concept of law “has little practical significance” is something that needs to be proven (hence the question addressed). To abide by a predictive theory of law – what the judges will do – is insufficient because in order to understand what they are doing, it is necessary for the analysis to be “comprehensive” enough to at least understand (or often presuppose) the concept of norms and legal order, otherwise it would be impossible to think of norms as reasons for action.

The identification of “valid” law requires a concept of validity. The reason why legal positivism could then be interesting for law and economics is that this question is stressing the systematic dimension of law (law is a set of norms that are interlinked to some extent). Kelsen, for example, is stressing the fact that legal orders regulate their own creation and application: this is the dynamic aspect of law (Kelsen 1967). If law is seen as a dynamic structure, it implies that each norm is produced according to a “superior” norm (or meta-norm), or at least that the procedure to create a norm is regulated by a norm in order to earn its validity (hence the necessity of a Grundnorm at the top of the system). This feature is not without impacts on economic analysis of law. Indeed, economic analysis is quite often focusing on the consequences of a primary norm *ceteris paribus*. In that case, it restricts itself to an economic analysis of a norm in “isolation” without regards to the system in which it belongs. When this happens, it is necessary to qualify the result of such economic analyses. Furthermore, the concept of efficiency becomes harder to figure out when the dynamic structure is taken into account. If, for example, a legislative process is supposed to be efficient, it does not mean that it cannot produce inefficient primary norms. However, are these primary norms really inefficient since they are produced by an efficient structure? (Lanneau 2016).

Rationalizing the Content of Norms and Assessing Consequences, the Blind Spot of Legal Positivism

For legal positivist, law is the product of authorities which are determining the “goals” of these rules. Rationalizing the goals is considered as “impure” in the Kelsenian system because it entails the use of methodologies that are considered as external. Even more, an analysis of the consequences is required if a legal order is supposed to be purposeful. This situation “forces the question, do these legal rules achieve the objectives at which they aim, and would alternative rules do any better?” (Bix 2004); then law and economics could be used in all of its dimensions to inquire into norms, sub-systems of norms or the whole system of norms.

And Kelsen does not seem opposed to an inquiry into the reason for norms that do not necessarily appear in legal propositions; it is simply not the task that he is trying to achieve. He even recognizes that: “For the legal norm obliges the debtor not only and, perhaps, not so much in order to protect the creditor, but in order to maintain a certain economic system” (Kelsen 1967). It is then possible to suggest a rationale for norms or systems of norms, and economics is one of these rationales.

Conclusion

Understanding the proper domain of validity of both legal positivism and law and economics is a prerequisite for clear thinking. Moreover, understanding the blind spots of both approaches could help to enrich both and contribute to developing a true law and economics approach and not a mere economic analysis of law. This path remains to be fully taken but should, with time, help European academics to seize the potential of law and economics.

borrowing is usually the driving factor in legal change, reasons for dissent, repeatedly manifested, among others, by Pierre Legrand, were rooted on the denial of the same possibility of transferring rules and laws from one legal order to another (Legrand 1996).

Regardless of the academic discourses on whether legal transplants are sustainable as a notion in the legal theory, they are common practice. Nevertheless, the degree to which new laws are stimulated by foreign examples can vary. A frequent and often justified criticism is that imported laws are not suited to a certain local context.

Legal borrowings and transplants simply occur, though they can be more or less successful and effective, more or less persistent.

Legal Transplants

Gianmaria Ajani
Department of Law, University of Torino,
Torino, Italy

Definition

The term “Legal transplants” is commonly used to designate the dissemination of legal models from an exporting legal order to a receiving one.

In a wider perspective, reception, transplants, or borrowings may either refer to the process, or to the results of a project of legal reforms, which is in turn initiated by a plan of legal change based upon an imitation of laws, doctrines and theories, and judicial decisions, already in place in different legal orders.

Within the fabric of such terminology, the notion of legal transplants has been, for the last four decades, most central. This is also due to a successful and widely discussed book by the legal historian Alan Watson (1974), which is devoted to a specific set of borrowings within the realm of private law. While the success of Watson’s study emerged from the plain recognition that

Dynamic Approach to Comparative Law

Comparative lawyers have paid a particular attention to the phenomenon of legal transplants.

At first, the traditional approach envisioned a static mapping of the major legal systems (David 1985): following this thread, which was the custom in the first part of the last century, national legal orders were classified and combined within larger groups, on the basis of the so-called “styles of legal families,” or common traits (Zweigert and Kötz 1998). Such an approach, still influenced by strands of national positivism and by the recognition of enacted legislation as the center of the observation, certainly removed some of the emphasis previously placed on the aspect of intra-system dissemination of rules.

Where mixed systems, such as South Africa or Israel, were recognized, they were presented as exceptional to the monolithic coherence of the several state legal orders, based mainly on the historical development of national law.

A new approach to comparative law was inaugurated in a seminal study by Rodolfo Sacco (1972, 1991). Sacco, progressing from the contributions of Gino Gorla and Rudolf Schlesinger, shifted the focus from the static description of legal orders to a dynamic reading of the borrowings, which nurture them. If we consider Sacco’s starting point, comparative law presupposes the

existence of a plurality of legal rules and institutions. A comparativist is called to study them in order to establish the extent to which they are identical or different. The analysis of legal formants, that is the different formative elements of a legal rule, has the aim to discover how the “jurist concerned with the law within a single country examines all of these elements and then eliminates the complications that arise from their multiplicity to arrive at one working rule” (Sacco 1991, p. 22). A full understanding of legal formants and their interrelation allows us to ascertain the factors that affect the given solutions. This clarifies the weight that interpretative practices (grounded on scholarly writings, on legal debate aroused by previous judicial decision, etc.) have in molding the actual outcome of the rules.

It follows that circulation of norms, borrowings, and transplants, all that is considered to be part of a process of reception, is the circulation of formants. By recognizing fragmented circulation, comparative law challenges the positivistic idea that reduces legal borrowings to the dissemination of enactments. The fragmented nature of the process leads to very different situations: In one case, the rule contained in a doctrinal formant may be able to circulate and finally be embodied in a statute.

In other circumstances, the influence may remain at the level of homogeneous formants (i.e., case law to case law).

Legal Borrowings, Global Harmonization, and the Neutrality of the Law

Historically, the idea of law’s indifference toward specific social contents has been kept alive by the millennial success of Roman law.

Subsequently, colonization only served to confirm the fact that different societies may be governed by similar laws. A more recent reappraisal of the idea occurred in the case of transition from Sovietism to market, in the wide area formerly under communist rule.

The belief that law or, more precisely, some areas covered by private and business law can be

independent, or neutral, with respect to a given society is closely connected to the idea that law can have a predictable impact on economic performance. The idea is not new at all: in fact it is linked with the spread of modern rationalism, which secured the transition from natural law to rational law. Similarly, the process of searching for the best legislative practice beyond national borders in order to support the modernization of a national legal system is not a new strategy. In this respect, one may recall the famous polemic originated two centuries ago between two great German legal scholars, Anton F. Thibaut, on the one hand, suggesting that the German states had to imitate French “rational” codification of private law in order to support modernization, and Friedrich K. von Savigny, on the other hand, contrasting the proposal, on the basis of a temporary cultural inadequacy of German legal scholarship.

During the last 20 years, after the waning of ideological confrontation, the resurfacing of a search for national identities based on culture and civilization has made the idea of neutrality of certain areas of the law somehow more difficult to defend. As a result, the recognition of what can be considered more neutral, or less dependent on society, has changed.

All throughout the period of the East-West confrontation, family law was deemed to be more indifferent (and therefore the comparison was inspired by a search of similarity), while economic and commercial law was taken as absolutely unfit for comparison. Today, in the age of globalization, many commentators would subscribe the statement that it is a smoother process to harmonize, for example, company law than the legislation addressing family law issues.

In order to draw closer to assessing the relevance of the principle of indifference toward legal change, one should begin by distinguishing between two possible ramifications: indifference as a political issue and indifference as a cultural issue.

As a political question, the principle of the law’s indifference to the social context has gained strength since the end of the cold war. While the idea of the uselessness of communist law “in

its entirety” (*tabula rasa* principle) was being affirmed by the governments and the international institutions supporting legal reforms in post-communist states, the neutrality principle characteristic of Western private law was put forward.

The adoption of an ideal model of market development by the neoliberal economists has significantly influenced the actions of the European Union and the international financial institutions, such as the World Bank and the International Monetary Fund, both seeking to speed up the process of market integration. Yet, this brought the focus of the discussion away from the institutional perspective: The “best” legal transplant appears to be a denationalized one, clothed in an appearance of objectivity that thwarts local resistances based on cultural identity. This separation of the action of the law from the actual role played by institutions is central to an understanding of the many failures of legal reform agendas.

It is, in fact, rather difficult to conceive a role for a legal transplant without considering how local institutions work. For any single new rule that is introduced, role-occupants will necessarily consider, more or less consciously, a set of pre-existing conditions that are country-specific and often non- or sub-formalized.

As a cultural question, the idea of indifference is indebted with a couple of phenomena that have significantly marked the last decades of the twentieth century:

- *Postmodernism*: There is something paradoxical in the fact that by insisting on the incommensurability of phenomena such as culture and social behaviors, postmodernist theories, which were perceived as a defense of localism against the forceful nature of globalization policies, by making relative the belief in justice and by criticizing the principle of objectivity in the law, have contributed to paving the way to the spreading of globalized formal regulations.
- *Uniformization of the law*: The success (both in terms of absolute numbers of initiatives, and of the number of adhering states) of the recourse to international conventions has brought the style of international law into the process of

legal transplant. This has important effects on the issue of neutrality, as international law was traditionally characterized by indifference toward domestic diversity and cultural differentiations: the traditional approach to the cultural issue practiced by international lawyers stresses the recognition of “similarities in economic development” (in such a sense, for instance, Thailand and Kenya are similar, in spite of evident cultural difference).

In other words, the technical side of neutrality is expressed by the language of performances and functions, while the cultural difference calls for an explanation in terms of history. International law deals with the former, while the latter is left to the realm of local policies.

This approach, however, has been subjected to a set of critiques (Kennedy 2003).

A first argument points to the fact that it is almost impossible to discern local from foreign cultures; even within a short span of time what was an alien culture may become local, as illustrated by the important cases of languages and arts, during every historical era and everywhere in the world.

Second, the “cultural exception” is of relevance to the context of economic issues. In particular, there are significant cases where the State actors use cultural issues to protect what are perceived to be national economic interests.

Finally, legal culture is encompassed by the more general definition of culture; the isolation of local legal culture from the process of legal transplants verges on the absurd. As the comparative law analysis has demonstrated, the dissemination of rules and legal change occur with the active involvement of legal doctrines. This is usually classified as interpretation, but it would be more accurate to speak of “interdoctrinal legal transplants.”

Transplant of Vague Notions

In contrast to what was common practice until the middle of the last century, when the process of legal reform via legal transplants occurred mainly

from state to state, at a slow pace, and generally through the vehicle of legal scholars, an important portion of the dissemination today is entrusted to supranational institutions, such as the International Monetary Fund, the World Bank, and the European Bank for Reconstruction and Development. These institutions support intergovernmental agreements aimed at fostering legal reforms and introduce a matrix of soft laws, proposals, and recommendations for legal change.

In the past, a new statute, a code, or a constitution was adopted or emended on the assumption that the “prestige” of the imported set of rules was sufficient to legitimize the change.

Today, the process of legitimizing the legal reform cannot be built upon a simple and circular argument such as the reputation of the foreign model.

Within this new situation, we notice that the process of legal transplantation is characterized by the recourse to vague formulas, such as *due process*, *governance* (and *good governance*), *reasonableness*, *rule of law*, *transparency*, and *accountability*.

We can identify three factors that have contributed to this shift in the building of legitimacy for the phenomenon of legal transplantation:

- Functionalism
- Cultural resistance
- Recourse to “naïf language”

As far as functionalism is concerned, one may consider replacing evaluations from the side of the borrower, based upon historical ties and cultural appreciation, with assessment built on the assumed utility of a set of norms targeted toward improving economic performance.

Cultural resistance concerns the increased awareness, from both sides (importer and exporter of legal rules), that local diversity is (or can be) an obstacle to an open transfer of rules among different legal orders.

When mentioning “naïf” (i.e., nontechnical, ordinary) language, one may recall the use of general terms and concepts that characterize law-making as practiced by some institutions. As an illustration, we can consider the case of the

European Union: If we examine the style of EU laws we cannot fail to notice that, while drafting directives and regulations, the EU institutions do not feel the obligation to adhere to the system of concepts and doctrines practiced at state level by local jurists.

This approach has led, in the last 15 years, to a proliferation of the use of vague notions and to their inclusion within the rhetoric of “good governance for the market.” Furthermore, because broad formulas expressed in ordinary language are more palatable to the media, a bundle of concepts whose juridical/technical content is far from certain became the paradigm for assessing the modernization of a legal system.

Let’s consider some examples: What is, for instance, the actual meaning of the slogan: “Russian law today is based on the US model of corporate governance”?

It is easy to grasp the symbolic meaning of the statement: Those involved in reforming Russian law indicate that the Russian commercial law has accomplished its renewal from plan to market. By proclaiming the adoption of the US pattern for corporate governance (whatever its contents can be), it is also implied that the economic system is able to become as sophisticated as the ones where corporate governance based on US law is in operation.

Such a symbolic significance, however, does not shed a lot of light upon the casual links between the nature of the market and the contents of the rules: Is it from a particular market that the corporate governance has come into effect, or, the other way round, is it the particular organization of the market, with its constraints and freedoms, that originated such a model for corporate governance?

Another relevant example concerns the notion of the “Rule of Law.”

The lip service paid to the rule of law idea by many constitutions adopted, for example, in the Russian Federation or in the People’s Republic of China during the last 20 years, acts as a legitimization for legal and judicial reform and for intrusions inspired by those who formulate, know, and possess the taxonomy of reforms currently attached to the vague notion under scrutiny.

The insistence in reproducing the rule of law blueprint within constitutional texts also demonstrates that the professionals who organize legal reforms in the new post-Soviet Countries “are part of the West,” and share the so-called Shihata’s doctrine (named after the former General Counsel of the World Bank). The doctrine is based on a global generalization of Max Weber’s assessment of the role of rules and institutions for economic development.

Following such a design, the process of transplanting new laws is conducted by following two different steps: Bringing the rule of law and other related and vague notions to the attention of reformers; and conveying operational rules as necessary consequences that follow the adoption of rule of law as a “constitutional standard.” The process is manifest in the pronouncements made by major financial institutions, as well as by other institutions, such as the European Union, or the World Trade Organization.

Its recognition, however, should not lead us to the immediate identification of that two-step process as a sort of machination; using vague notions in order to ease the bypassing of cultural sovereignty could, in fact, be part of a plan, aimed to an intense homogenization of the rules that are conceived by the International Financial Institutions as conducive to liberalization of trade, but this is not the only possible explanation of the success of the rule of law notion.

Besides the desire to avoid negotiations in the process of legal transplant, other reasons can be spent, such as the spreading, among the agencies exporting legal rules, of a practice of legitimization for their action based on the recourse to broad and consensus-making formulas. And if we share the élitarian explanation for the success of legal transplants suggested by some comparativists (Watson), we will assume that a recourse to vague notions is welcomed by the lawyers in the recipient country, who share the interest of the exporters in overcoming local resistances against transplants.

Whatever the case is, strategy or serendipity, it is very reasonable to assign to the mentioned vague notions the role of reducing transaction costs arising from the process of legal transplant.

Legal Transplants and International Law

The transnational institutions’ officials that are active in supporting legal transplants have inherited an obsession with the establishment of worldwide recognized norms from international lawyers. To attain the objective of a global recognition of international norms in a world where cultural diversity claims are reaching their climax, there are only two, rather conflicting, paths. The first entails recourse to hyper-specialized language, which is assumed to be, similar to the language of technicians and engineers, neutral and unrelated to local considerations. The alternative lies with the use of ordinary language, which does not dabble with the jargon of local experts.

The rule of law has not only become a substitute for discussion on the effects of development policies, but also a means to avoid, at least during the initial stages of dialogue between donors and recipient countries, an embarrassing confrontation on the “operational meaning” of widely debatable political notions such as democracy, pluripartitism, and judicial independence. Such an opportunity has proved to be useful not only for the international financial institutions seeking to sidestep problems with their mandate, but also for the EU institutions, involved in the extremely delicate issue of outlining the conditions for the Union enlargement toward East.

It is very clear, at this point, that the problem of providing exact definitions has been simply postponed by the urgency of having to adopt legal reform programs without too much discussion about contents or possible effects on the concerned domestic legal and economic system. Vague notions are useful as long as they respond to the persistent problems of globalization: scarcity of time and lack of consent. If this is the context, the strategy of legal transplants and reception requires that the rhetoric of the vague notions be characterized by a neutral style. Normative arguments follow at a later stage, once the sovereignty barrier has been circumvented: The process of transplanting rules assumed to be necessary for a good development of the market will be presented as a natural derivation from the vague notion itself.

What lies at the core of the practice of legal transplants is the contamination by the “style” of negotiation that characterizes both international conventions and supranational legislation. Indeterminacy of language allows the reaching of consensus (when required) and obtaining agreements within a reasonable span of time. In other words, a vague language facilitates the following:

- Postponing the tackling of obscure issues and puzzles related to implementation
- Avoiding a dive into details of distributional nature, and choices connected with introduction of good governance standards
- Putting off the resolution of arguments deriving from translation
- Empowering external lawmakers, who ground their legitimacy on a set of previously adopted vague formulas
- Keeping the governance of macroeconomic decisions under the control of “external standards provider” (e.g., the EU, during the process of enlargement toward Central and Eastern Europe)
- Producing an output ostensible to the donors (codes, laws, conventions, and the like)

These facilitating factors support an uncontested transplant of laws that are considered necessary for market functioning and economic development.

At the same time, however, they produce a false image of law as a static, neutral set of rules of universal application, under the unique condition that a commitment to the rule of law is expressed by the governments.

Conclusion

Both comparative analysis and functionalist methodology tell us that different rules may lead, through interpretation, to analogous results. The actual insistence on extensive harmonization is originated by a deficit of confidence in the capability or in the willingness of the local governments to set in place the enactments that are considered to ease economic development.

A reduction of the emphasis on the absolute necessity to imitate the formal contents of the laws, and a more convinced recognition of the role played by institutions in modeling the rules: These two actions, when taken together, can reduce the friction that characterizes the process of legal transplants.

In doing this, an important contribution may derive from institutional law & economics: It is indeed essential that, within the process which prepares legal change, every single macroeconomic recipe, for instance, the recognition of freedom of competition as an element of good economic performance, be separated from the several possible legal designs that it can assume. This should be based on the recognition that, historically, a successful transition from stagnation or underdevelopment to economic development was originated by a peculiar blend of mainstream economic theories and local regulations.

Legislative Television

Franklin G. Mixon Jr.
Center for Economic Education, Columbus State University, Columbus, GA, USA

Abstract

Seminal studies describe legislative television as an advancement in political information technology that is used by incumbent legislators for protection against political challengers. Today, legislative television spans much of the globe, creating both intra- and international differences that have made the study of the impact of legislative television on the political process something akin to a natural experiment. This entry discusses some of the studies that make up this branch of the law and economics literature, with particular focus on how the presence of television in a legislature impacts turnover rates, session lengths and the popularity of various parliamentary procedures.

Definition

Legislative Television refers to the televising, either in real time or on a tape-delayed basis, of a government's (local, regional, or national) legislative process.

Televising Legislatures in the U.S. and Beyond

In a study whose primary focus is *not* the televising of legislatures or politics and politicians, Cowen (2000, p. 51) cuts to the heart of the subject, stating:

Successful politicians must use television and compete with popular culture for audience attention. Leaders therefore court voters by entertaining them and making them feel good. This strategy may win popularity and increase votes. . .

It is the general theme expressed above by Cowen that seminal studies on legislative television, either from a US or international perspective, have used as a theoretical foundation for modeling the behavior of politicians in the world where their daily activities are televised for thousands, or even millions, of constituents. The seminal studies by Crain and Goff (1986, 1988), with supplemental work by Greene (1991), describe legislative television as an advancement in political information technology – one used by incumbent legislators for protection against political challengers – thus placing the subject in the broader law and economics subcategory known as the economics of information (Stigler 1961; Nelson 1970, 1974, 1976; Telser 1976).

According to the National Conference of State Legislatures (ncls.org), 32 of the 50 states in the USA now offer televised coverage of state-level legislative sessions. In terms of national governments, Canada and Mexico join the USA, where the Cable-Satellite Public Affairs Network (i.e., C-SPAN, C-SPAN2, and C-SPAN3) operates, and most of Europe in offering televised broadcasts of legislatures. These continents are, however, different from Asia and South America, where relatively few countries now provide legislative television. Thus, from an academic perspective,

these intra- and international differences have made the study of the impact of legislative television on the political process something akin to a natural experiment and, therefore, fertile ground for modern scholars of law and economics.

The comprehensive work of Crain and Goff (1988) begins with an empirical analysis of the impact of legislative television at the state level (in the USA). They find that in smaller, less diverse (in terms of population) states, wherein legislative television is theoretically useful in protecting incumbents, the presence of television cameras serves to reduce the number of winning challengers in state house elections. This result carries to the federal level, given Crain and Goff's (1988) finding that legislative television coverage, in this case C-SPAN coverage, served, in more homogeneous districts, to increase the typical US House of Representatives incumbent's vote share. Mixon and Upadhyaya (2003) carry this theme forward in finding that the presence of C-SPAN cameras in the US House has, throughout its history, reduced turnover in that legislative body. This result not only confirms the incumbency-protection hypothesis in Crain and Goff (1988), but it also supports Mixon and Upadhyaya's (2002) earlier finding that the presence of C-SPAN2 cameras in the US Senate has, throughout its history, reduced turnover in that legislative body. These results complement the reverse causality found in Crain and Goff (1986, 1988) and Tyrone et al. (2003), wherein incumbents, seeking electoral protection from challengers, choose to adopt the televising of their legislative sessions.

Digging further into how incumbents are able to use legislative television to their advantage, Mixon (2002) and Mixon et al. (2003) find that US Senate filibustering is, in the presence of C-SPAN2 cameras, more effective as a form of low-cost political advertising for incumbents and, therefore, occurs with greater frequency. Similarly, Mixon and Upadhyaya (2003) find that one-minute speeches in the US House of Representatives increased in value and frequency in the presence of C-SPAN cameras. Given these results, it is not surprising that studies indicate that the presence of television cameras lengthens

legislative sessions, which, in the case of the US Senate, has been estimated to be an additional 63 min per recorded vote (Mixon et al. 2001; Mixon and Upadhyaya 2003). As Kimenyi and Tollison (1995) show, longer legislative sessions, such as those occurring in the presence of legislative television, come with a secondary effect – more complex legislation and greater government spending.

Where does this research program go from here? The short answer is *outside of the USA*. In one of the first published studies in this category, Soroka et al. (2015) find that televising the Canadian House of Commons has not had any discernible effect on politicians' behavior. This result confirms those in unpublished studies referenced in Soroka et al. (2015) indicating that the presence of cameras in the British House of Commons has had little, if any, effect, while the televising of Canada's House of Commons has impacted only the attire and within-session attention of the members of that legislative body. Clearly, there is much yet to learn about the law and economics of legislative television.

Lender of Last Resort

Uwe Vollmer

University of Leipzig, Leipzig, Germany

Definition

A lender of last resort (LoLR) is an institution, usually the central bank (CB) or a public deposit insurer (DI), which offers emergency financial assistance to commercial banks particularly during a financial crisis. In most cases, financial assistance means provision of liquidity to a single financial institution or to the financial market as a loan (liquidity assistance), usually against first-class collateral. Sometimes, the LoLR also recapitalizes commercial banks and provides risk-capital support that has not to be paid back (bank bailout).

Origin

The need for a CB to provide liquidity assistance was first mentioned by Henry Thornton (1802/

1939) and advanced by Walter Bagehot (1873) who elaborated the 9 principles applied to a policy of an LoLR. He proposed that the Bank of England should announce in advance its readiness to lend against collateral any amount to an illiquid but solvent financial institution at a penalty rate of interest. Bagehot suggested that during a financial crisis the central bank should lend freely at interest rates higher than precrisis levels to any sound borrower. Quality standards on collateral should be relaxed during crisis, but banks without good collateral were assumed to be insolvent and should be allowed to fail (Freixas et al. 2000a).

During the twentieth century authorities in many countries have acted as LoLR (Bordo 1990). Recent examples comprise the Swedish Riksbank and particularly the Bank of Japan which during the financial crisis of the 1990s provided substantial liquidity assistance to commercial banks; moreover, in Japan the Ministry of Finance injected almost 25 trillion yen of public funds into the banking industry (Nakaso 2001; Bebenroth et al. 2009). After the collapse of Lehman Brothers in September 2008, CBs of all major OECD countries conducted expansionary open market operations and provided liquidity assistance to single banks and other authorities conducted extensive recapitalization schemes (Petrovic and Tutsch 2010).

The need for a CB to provide liquidity assistance was first mentioned by Henry Thornton (*An enquiry into the nature and effects of the paper credit of Great Britain* (ed with an introduction by FAvon Hayek). George Allen and Unwin, London; 1802/1939) and advanced by Walter Bagehot (*Lombard street: a description of the money market*. Dodo Press, London; 1873) who elaborated the principles applied to a policy of an LoLR. He proposed that the Bank of England should announce in advance its readiness to lend against collateral any amount to an illiquid but solvent financial institution at a penalty rate of interest. Bagehot suggested that during a financial crisis the central bank should lend freely at interest rates higher than precrisis levels to any sound borrower. Quality standards on collateral should be relaxed during crisis, but banks without good collateral were assumed to be insolvent and should be

allowed to fail (Freixas et al. *J Financ Serv Res* 18(1):63–84, 15 [2000b](#)).

Bank Runs and Interbank Market Failures

The need for liquidity assistance by an LoLR results from the fact that commercial banks are fragile institutions that simultaneously offer very liquid deposits to their customers and invest funds received into profitable but illiquid projects. With this kind of liquidity creation, banks are subject to the possibility of a bank run, i.e., a situation where all depositors, even those without actually facing liquidity need, want to withdraw their deposits. Because deposits are subject to a “sequential service constraint” and are paid out in full on a “first come, first served” basis, depositors have to stand in front of the line to get their deposits repaid. A run may then result from a coordination failure among depositors, i.e., when sunspot events make depositors withdraw deposits because they believe that other depositors will do so (Diamond and Dybvig [1983](#)). Moreover, a bank run can also occur by changing fundamentals such as expectations that a bank’s capital cushion may be totally spent when assets devalue (Jacklin and Bhattacharya [1988](#)). Since the bank’s assets are not ready marketable and short-run rewards from “fire sales” are small, a run always results in an insolvency of an otherwise sound bank.

Interbank markets may shield individual banks against the risk of a bank run because they allow for a reallocation of liquidity among financial institutions. As long as individual bank’s liquidity needs cancel out, banks with liquidity surpluses may lend to other banks with a deficit, provided that they are considered creditworthy. If a run on a single bank, however, results in an aggregate liquidity shortage, an additional source of liquidity from outside the banking system is needed. If interbank markets function efficiently, the CB may provide additional liquidity through open market operations, leaving the allocation of liquidity to the interbank markets. This is, however, not sufficient during a financial crisis when interbank markets do not work smoothly, because

market participants perceive increases in counterparty risk or liquidity risk (Flannery [1996](#); Freixas et al. [2000a](#); Eisenschmidt and Taping [2009](#); Heider et al. [2009](#)). Then, the LoLR is forced to provide liquidity assistance to single institutions because the failure of an illiquid bank may have systemic consequences.

Systemic Crises

A run on a single bank may spread over the banking system if depositors consider the failure of another bank as a signal that their own bank is in trouble and withdraw their funds. If this occurs because depositors suspect similarities between banks, i.e., only depositors of banks with similar types of business withdraw while others do not, the contagion is called information based (Chari and Jagannathan [1988](#)). If the failure of the first bank leads to widespread run on banks without any assessment of similarities or dissimilarities, the situation is called pure panic (Kindleberger [1989](#)). The interbank market may also be a source of financial contagion when liquidity needs of one bank are sufficiently large to create an economy-wide shortage of liquidity, which then spills over to other banks (Allen and Gale [2000](#)). With extensive interbank exposures, the failure of one bank may have immediate effects on other institutions, especially if interbank lending is unsecured.

Systemic banking crises may be tremendous costly for society because they threaten the ability of the financial system to fulfill its basic functions and to provide liquidity. While this may justify LoLR liquidity support, it may also get into conflict with the CB’s ordinary monetary policy which is aimed at controlling interest rates or medium- or long-run monetary growth and inflation (Goodhart and Schoenmaker [1995](#)). Though emergency financial assistance is meant to satisfy extraordinary short-term increases in liquidity demand of depositors, CBs often have difficulties to exit from these measures. Especially if LoLR policies are extended on terms more favorable than are available in the interbank markets, banks may have an incentive to use the CB’s

standing facilities too extensively, making it difficult to keep the control over base money supply.

Solving this problem implies separating emergency liquidity assistance from monetary policy and to assess LoLR function not to the CB but to the public deposit insurer. Since the DI has to repay deposits in case of a bank failure, its incentives to provide financial assistance differ from those of the CB, and the optimal allocation of the LoLR functions between authorities depends on the size of the liquidity shock. The central bank should act as LoLR when a bank's liquidity needs are small, but the deposit insurer should be in charge when they are large (Repullo 2000). Kahn and Santos (2005) further argue for allocating supervisory power to the deposit insurer and identify conditions under which centralizing LoLR and deposit insurance functions is inefficient. In particular, when incentives to share information are weak, the allocation of regulatory power across government agencies should be contingent on their respective comparative advantages in gathering and utilizing relevant information.

Bank Bailouts

While Bagehot proposed only to support illiquid but solvent banks, the distinction between solvent and insolvent institutions is often difficult to make, especially in a short period of time (Goodhart 1999). Moreover, it may be less costly to recapitalize an insolvent bank than allow it to fail, and the failure of an insolvent bank may have systemic effects on the financial system. Therefore, an LoLR may also consider it worthwhile to recapitalize insolvent banks in a bank bailout. Such bank bailouts include instruments that either applies off the balance sheets of banks (like guarantees) or instruments that alter their balance sheets. The latter comprise a recapitalization through the asset side of the bank's balance sheet (purchases of nonperforming loans or "toxic assets" which are transferred to a "bad bank") or a recapitalization through the liability side of the balance sheet (introducing

either fresh risk capital or junior debt from the LoLR).

Though an ex post recapitalization of insolvent banks may be welfare improving, it creates – as any form of insurance – moral hazard on the part of commercial banks and sets ex ante incentives for banks to assume excessive risks. Guarantees give banks an incentive to take similar risks, thereby reducing asset diversification inside the financial sector and increasing its vulnerability against common shocks; they also create incentives to take higher asset risks and to accept a higher leverage (Chaney and Thakor 1985; Acharya 2009). Besides, guarantees influence the banks' competitors since they allow the beneficiary bank to take higher risks thereby forcing its competitors to accept higher risks, too (Gropp et al. 2010). Recapitalizations either through the asset or the liability side give banks an incentive to invest in unduly risky assets and to reduce reserves while depositors lose incentives to monitor the behavior and performance of their banks and to exert market discipline (Kaufman 1991; Saunders and Wilson 1996; Demirgüç-Kunt and Huizinga 2004).

Penalty Rates

To prevent these adverse effects, the LoLR may provide liquidity only at a penalty rate, i.e., at an interest rate higher than the market rate. Demanding such a penalty rate, however, may aggravate the bank's solvency problem. It may also send signals to market participants that the bank is in trouble; this makes banks reluctant to apply for funds because they fear to be singled out as a weak institute. Moreover, charging a penalty interest rate may even give an incentive to bank managers to "gamble for resurrection," i.e., to invest in projects with higher risks and higher returns in the hope of surviving and getting out of trouble (Rochet and Vives 2004; Repullo 2005; Castiglionesi and Wagner 2012).

"Constructive ambiguity" may be an alternative device to constrain moral hazard on the side of banks. It can be defined as a situation where the

LoLR ex ante creates uncertainty as to whether, when, and under what conditions financial support of an individual financial institution will be provided. If the LoLR keeps secret whether or not financial support will be granted, banks will not know individually whether they will be rescued or not; moreover, this might avoid “imitation effects” within the banking sector. If the LoLR is ambiguous about the conditions of financial assistance, it keeps a bank’s shareholders and management uncertain about the costs they have to bear in the case of financial assistance.

The beneficial effects of “constructive ambiguity” assume that following a mixed strategy and randomizing the unconditional rescue of banks dominates pure strategies where the CB either always liquidates or always bails out a distressed bank. If a bank failure has systemic consequences, the optimal strategy chosen by the LoLR depends on the size of the bank in trouble. The LoLR should set an upper limit for the size of the uninsured bank debt and never rescue banks that exceed that limit; constructive ambiguity should be applied to the rest of the banks (Freixas 2000). In a dynamic setting the effect on moral hazard is complemented by adding a value effect because rescuing a bank increases the current value of future bank profits and that increases the bank’s incentives to improve loan quality. Then, a mixed strategy is never beneficial, and the LoLR should always follow a pure strategy, i.e., rescue a bank if the value effect dominates and liquidate otherwise (Cordella and Yeyati 2003).

Private Sector Solutions

If “constructive ambiguity” is ineffective as a check on moral hazard, concerted private sector lending, organized by the CB, or private bank mergers and acquisitions, promoted by bank supervisors, could form alternatives. Orchestrated liquidity support operations may overcome the market’s coordination problems by encouraging a dialogue among banks or by imposing pressure on surplus banks to lend; this may be warranted if the CB has superior information about the banks’

solvency (Freixas et al. 2000a). Promoting takeovers of weaker institutions by solvent banks results in larger rents for the incumbent banks and creates additional incentives not to invest into gambling assets and to remain solvent (Perotti and Suarez 2002; Acharya and Yorulmazer 2008). Private sector solutions, however, are difficult to implement if the number of banks is large, market entry is easy, and the degree of competition in the financial sector is high. They are more probable to occur in financial systems with limited competition in banking, as during the 1970s in, e.g., Germany where after the failure of “Bankhaus Herstatt” liquidity assistance was organized as a private club (Beck 2002).

Leniency Programs

Karine Brisset

Centre de Recherche sur les Stratégies Economiques, University of Franche-Comté, Besançon, France

Abstract

Article 101 of the Treaty on the Functioning of the European Union prohibits cartels and other antitrust agreements that reduce or eliminate competition between firms. Leniency programs are an important investigative tool which give cartel's members incentives to report their cartel activity and cooperate with competition authorities. We present their main objectives, their development in different countries, their direct and indirect effects and how these programs could be improved.

Synonyms

Amnesty Programs

Definition

A leniency program consists in canceling or reducing any fine or other sanctions against companies, engaged in an illegal cartel, when they report strong evidence of their activity to a Competition Authority.

Leniency program's objectives

Across the world, one of the main objectives of antitrust authorities concerns the fight against illegal cartels. For that purpose, they conceive new tools to prosecute them and to increase their effectiveness. For more than 30 years, leniency programs constitute a major innovation applied by many competition authorities to fight cartels. These programs were first applied in the USA in 1978: the Amnesty Program. Currently, following the success of the American system, different

leniency programs are in effect in most advanced countries (most of the European member states, e.g., Germany since 2000 and France since 2001, Japan, Australia, New Zealand, Canada, China, South Korea, etc) and also in some developing countries. More than 50 countries have adopted different leniency programs.

For competition authorities, the main objectives behind this tool are:

- To increase their effectiveness in order to uncover cartels by relying on testimony from cartel's firms (enhance cartel detection, reduce the cost of prosecution)
- To prevent or reduce cartel formation by making cartel less stable, providing a greater incentive to deviate from cartel agreement and to immediately cooperate with authorities (enhance cartel deterrence)

History

The first American Corporate Amnesty Program, implemented in 1978, granted amnesty to the first company that gave strong evidence of its cartel before any authority's investigation. This program was unsuccessful (one case by year) for two reasons. Firstly, the amnesty depended on the discretion of the attorney general and required full cooperation of the applicant. Secondly, before any investigation by an authority, the individual risk of conviction is low, and the first American program gave no sufficient incentives to be effective. Hence, in 1993, the US Antitrust Division of the Department of Justice decided to review the program. The current program also provides full amnesty to the first company revealing information even after the authority's investigation has already begun and until the authority has sufficient evidence to condemn the cartel. Since this reform, there are one or two leniency applications per month.

In 1996, the European Union has also implemented its own leniency program. However, after 5 years of implementation, results appeared to be mixed. There was no certainty that the first applicant would obtain complete immunity. In

fact, less than half immunity was granted. In addition, once the Commission had begun an investigation, it was only possible to obtain a maximal fine's reduction of 75%. That is why the policy was first improved in 2002 and in 2006, with the objective of a greater transparency and certainty.

Current conditions are as follows:

- The Commission cancels any fines to the first applicant that provides substantial evidence of the cartel, allowing the authority to implement an investigation pursuant to Article 14 (3) Regulation No. 17 or to prove an infringement of Article 81 of the Amsterdam Treaty.
- In addition, if another company provides further information, it may receive a fine reduction (first firm to cooperate, reduction of 30–50%; second firm to cooperate, 20–30% reduction; other firms to cooperate, reduction of up to 20%).

Direct and Indirect Effects

Theoretical analyses have shown that leniency programs can increase the incentive to cooperate with authorities and may have a deterrence effect on collusion. However, they may also have a pro-collusive effect (Motta and Polo 2003). Indeed, leniency programs can increase the benefits of a cartel's member as they reduce the expected cost of the antitrust sanction. Hence, it is possible that the number of cartels increases because of leniency. Different empirical studies seem to conclude that the positive effect on cartel destabilization and on cartel deterrence dominates the pro-collusive effect. However, empirical identification is only derived with data from detected cartels (Brenner 2009; Miller 2009). Therefore, if the success of a leniency program depends on the number of uncovered cartels, it may mean that there are more current cartels and not necessarily more efficient prosecution.

To reduce this pro-collusive effect and to increase the effectiveness of a leniency policy, it is necessary to have higher sanctions against cartel's members and to have a real power of investigation. Indeed, if fines are weak and if the

probability of an investigation is low, the expected sanction will be low. Then, cartel's members will have no incentive to report to the competition authority because the risk of a conviction is weak. That is why, since 2002, the European Commission has decided to increase the level of fines against cartel's members. The maximal fine was doubled and represents 10% of a company's global turnover. This policy has increased the incentives to apply for leniency.

In contrast with the European program, the US program only grants exclusive amnesty to the first confessor. This strict program may create a "preemption effect" and may increase the deterrence effect (Harrington 2013). Indeed, even if one member thinks that the competition authority has a low likelihood to undermine the cartel, he may also think that another member may report and apply for leniency. In these conditions, he can have a strong incentive to quickly cooperate with authorities to preempt other members and to benefit from the fine's reduction. With the European program, second and third firms revealing strong evidence receive reductions in sanctions as well, but lower than the first confessor. Hence, the "preemption effect" exists but is less powerful than the one in the American program. It is also important that the gap in the reduction of fines be sufficiently great to increase the incentive to be the first to cooperate.

Can a Ringleader Apply for Leniency?

In the current US leniency program, a firm may only be eligible for amnesty when it is not a "ringleader." This clearly means that it is not at the origin of the cartel and that it has not invited any other firm to take part in the cartel (organize meetings, communication between cartel members, etc.). The first European leniency program, between 1996 and 2002, applied discrimination to the ringleader, too, but it was less strict: a ringleader was not illegible for full amnesty but could only have smaller fine reduction between 10% and 50%. However, the current program, following two revisions in 2002 and in 2006, is more

accurate and allows any cartel's firm, even a leader in the cartel, to benefit from full immunity provided it is not the cartel's instigator (which organizes and initiates the activity).

What is the economic impact of excluding the ringleader? If a firm, as a ringleader, is excluded from amnesty, it increases his potential sanction's expected cost in comparison with other members. Then, this ringleader can ask the others for a monetary compensation. This can create an asymmetry between this firm and the others and may decrease the sustainability of the cartel. Indeed, the result depends on the probability to be reviewed by the competition authority (Bos and Wandschneider 2011). If this probability is rather low, including the ringleader in the program may increase the probability of a successful prosecution. In contrast, if this probability is rather high, it may be better to exclude the ringleader to reinforce asymmetry with others.

How to Improve Leniency Programs?

Since the first American leniency programs, many measures have been adopted to improve their efficiency.

Leniency Program for Multimarket Firms

Multimarket contacts can facilitate the sustainability of collusion (Bernheim and Whinston 1990). In practice, cartels may concern many markets. That is why in 1999, the USA has adopted **the Amnesty Plus program**. Its objective is to convince a firm convicted in a first market to report evidence on a collusive agreement in another market. Hence, this firm could obtain amnesty as a cartel member in the second market if it is the first one reporting this cartel and a fine's discount as member in the first cartel. Theoretical conclusions on the Amnesty Plus reform are not clear. Indeed, it has two opposite effects on companies' incentive to collude. It may reduce the deterrence effect by increasing the sustainability of multimarket collusion. However, it can reduce the cartel's expected duration by increasing the risk of report after the detection of the first cartel

(Lefouili and Roux 2012). If the program is rather lenient, it would seem that the procompetitive effect is stronger.

Leniency Program and Fight Against International Cartels

In practice, many cartels concern international markets and may be prosecuted by different jurisdictions. In the USA, 90% of recent fines for antitrust infringement result from international cartels. Information sharing among competitive authorities of different jurisdictions could increase fight against cartels, reduce the cost, and improve the effectiveness of an investigation (reducing time to obtain strategic information, improving exchange of strategic documents). However, information sharing between different authorities could reduce the effectiveness of leniency programs as well (Choi and Gerlach 2012). Indeed, confidentiality is essential and is a necessary condition to be credible and to protect the integrity of leniency applications.

A More Incentive System: Reward for Whistleblowers

In April 2005, the South Korean Fair Trade Commission has introduced a reward system to give more financial incentive for outsider whistleblowers to reveal information and provide evidence on secret cartels. Hence, in June 2005, an anonymous person who revealed a welding rod cartel, providing strong evidence, received a reward of \$63,700. In the USA, through the False Claims Act, there is a similar financial reward mechanism to fight fraud against the government, but not for violations of competition law. In Europe, no reward system for informers exists. Theoretical predictions suggest that rewarding cartel members for reporting is a powerful tool to deter cartel formation (Aubert et al. 2006; Buccirossi and Spagnolo 2006). It increases the risk of an individual deviation, bringing more incentive to report. It can also increase the cartel's expected cost because firms will have to "bribe" individuals to prevent them to report. However, a first experimental analysis concludes that rewarding whistleblowers does not further deter cartel

formation in comparison with traditional leniency (Apesteguia et al 2004). But a second one, assuming a dynamic setting, predicts that rewards increase cartel detection due to self-reporting (Bigoni et al. 2012).

Leniency Program and Administrative and Criminal Enforcement

In the USA and in South Korea, there are criminal sanctions for individuals engaged in cartel activities (custodial sentences). In the USA, since 1994, a criminal leniency has been implemented. Moreover, since 2004, an individual involved in a cartel can be imprisoned for up to 10 years. Most of European member states have the possibility to impose criminal sanctions on individuals for cartel conduct. For example, in France, individuals can face jail time for up to 4 years and may have a criminal fine for up to 35,000 euros. Moreover, some European states (UK, Ireland, and Austria) have both administrative and criminal leniency programs. In these countries, the competition authority will not prosecute an individual if he satisfies conditions for leniency. Other member states (Belgium, France, Germany, Slovenia, Estonia, Ireland, etc.) do not have any criminal leniency program. In practice, jail sentences are indeed rarely imposed. Moreover, currently, the law of the European Union does not provide for criminal sanctions, and each member state is free to impose its own system of penalties for antitrust infringements. In contrast, in the USA, there were many jail sanctions against chairmen of companies engaged in cartel activities. The idea is that jail sentences are a great disincentive for individuals to participate in a cartel. In Europe, some officials think that high administrative fines are sufficient to deter cartel conduct. Both mechanisms are indeed complementary. With an administrative leniency, the efficiency only depends on the incentive of cartel companies. With an individual criminal leniency, the impact depends on the objectives of an employee concerned by a criminal sanction, but it may also concern his company itself. Indeed, if the company anticipates the risk of report by its employee, it could have more incentives to apply for a corporate leniency.

Lex Mercatoria

Bruce L. Benson

Department of Economics, Florida State University, Tallahassee, FL, USA

Abstract

Lex Mercatoria, or the Law Merchant, generally refers to the customary rules and procedures developed within merchant communities to support trade in medieval Europe, without the assistance of government, although this system has had many names through its evolution. This system began to develop sometime in the early Middle Ages, but became widely recognized as commerce expanded in the eleventh and twelfth centuries. Lex mercatoria lowered transactions costs, and provided incentives to live up to promises, thereby allowing for widespread use of contracting and credit as commerce expanded. The customary law system developed behavioral rules based on customs, practice and usage within the network of merchant communities, but processes to encourage recognition, provide adjudication and generate changes in the rules. The primary impetus for recognition of the law merchant within the commercial sector were the positive incentives associated with maintaining reputations and repeated dealings, along with the potential of reputation sanctions (e.g., spontaneous ostracism) for misbehavior. Arbitration was probably the primary dispute resolution process, although merchants used other courts (particularly fair courts sometimes referred to as piepowder courts, market courts, urban courts and ecclesiastical courts) when they

were willing to base decisions on the law merchant. Change was generally initiated through bargaining and contracting, followed by emulation so that new rules spread. Various general principles of the law merchant became increasingly universal over time, although the system remained polycentric in many ways. One reason for polycentric characteristics is that authoritarian legal systems (e.g., royal law, urban law) strove to gain control over commerce and its regulation by imposing additional laws on merchants that often conflicted with the law merchant, forcing changes in merchant practice and usage. The success of such efforts varied over time and space.

Definition

Lex Mercatoria: The customary rules and procedures developed within merchant communities to support trade in medieval Europe, without the assistance of government.

Introduction to the Law Merchant

Ninth century documents suggest that merchants in parts of Europe used different legal procedures than local communities (Kadens 2004, 43). According to Notger of St. Gallen, writing around 1000 A.D., “merchants maintain that a sale made in a fair should be binding ... since it is their custom” (Volckart and Mangels 1999, 439). Greif (2006, 70) quotes numerous eleventh century documents illustrating “that the Maghribi traders ... employed a set of cultural rules of behavior – merchants’ law.” Such institutional arrangements continued to evolve as a system of customary law used by merchants and referred to as “merchants’ law,” “custom of merchants,”

“customary law of merchants,” “method of merchants,” “the way of the trade,” and “law of the fair,” but now regularly labeled *Lex Mercatoria* or the “Law Merchant” (*Lex Mercatoria* terminology also is applied to rules and institutions supporting modern international trade, but the focus here is on the medieval system). A large literature describing and analyzing medieval *Lex Mercatoria* exists [for example, *The Little Red Book of Bristol* written sometime around 1280 (Bickley 1900; Teeter 1962; Basile 1998); Stracca (1553); Malynes (1622); Marius (1651); Zouche (1663); Mitchell (1904); Bewes (1923); Trakman (1983); Berman (1983); Benson (1989, 1999, 2011, 2014a, 2014b), and Milgrom et al. (1990)], although there also are critics of the medieval Law Merchant story [e.g., Volckart and Mangels (1999); Kadens (2004, 2012); Sachs (2006); Michaels (2012); criticisms are not addressed here, but see Benson (2011, 2014a, 2014b)].

Among factors that encouraged Europe’s advance into the “High Middle Ages” were technological innovations reducing labor requirements in agriculture, allowing specialization, and resulting in substantial expansions in production and trade. Growing numbers of merchants from widely dispersed areas of Europe traded with one another, primarily at fairs. Transactions costs were high as merchants had different cultural and ethnic backgrounds. Such transactions costs could be reduced with legal arrangements to increase credibility of merchant promises, but to the degree that states existed, they were “unable to supply the basic services of the state” (Volckart and Mangels 1999, 435), including enforcement of commercial contracts. In this context, “the basic concepts and institutions of ... *lex mercatoria* ... were formed” in eleventh and twelfth century Europe by merchants themselves (Berman 1983, 333).

Customary Law

Lex Mercatoria was customary law: a system of rules and governance processes that

spontaneously evolved within merchant communities and recognized because of trust arrangements, reciprocities, mutual insurance, and reputation mechanisms, including ostracism threats. Negotiation (contracting) was the most important source of legal change. Agreements only applied to the parties involved, but others voluntarily adopted changes if they appeared beneficial. As resulting behavior spread it became expected, and a new rule was recognized. Individuals also could unilaterally adopt behavior which others then observed, came to expect, and emulated, or an arbitrator/mediator might offer an innovative solution to a dispute, followed by voluntarily adopted by others.

Contracts and Credit

Face's (1958, 1959) examination of twelfth and thirteenth century documents demonstrates that nonsimultaneous (contractual) trade between Northern and Southern European merchants was the overwhelming dominant practice at the Champagne fairs, the most important European fairs at the time. Six annual fairs were held sequentially in different Champagne towns, each lasting about 52 days. These fairs included: (1) eight "entry" days when merchants set up their shops, (2) ten days for exclusively trading cloth, (3) eleven days to trade cordovan (leather) goods, (4) nineteen days when goods sold by weight, such as spices and dye-stuffs, were traded, and (5) four days for settling accounts and drawing up "letters of the Fair" (Face 1958, 427). Thus, Southern European "caravan" merchants bought northern wool and linen before selling their spices, dyes, or cordovan, using promissory notes or letters of credit from money lenders (or simply verbal promises) accepted by French, German, English, and Flemish merchants. These financial instruments were negotiable so northern merchants could buy goods from any other merchant or retain instruments for later use. Documents also demonstrate that caravan merchants bought spices, dyes, and cordovan on credit in Mediterranean ports and made large

numbers of cloth sales to *draperii*, again often on credit. Similarly, Northern merchants bought and transported cloth to Champagne, sold it, and bought spices, dyes, and/or cordovan to transport and sell, almost entirely through the use of credit. Merchant also contracted with agents or partners "to act in his place, to fulfill old obligations, and in many cases to undertake new ones" (Face 1958, 431), and with professional freighters who transported trade goods to and from fairs (Face 1959). Clearly, as the *Little Red Book of Bristol* c. 1280 (Basile 1998, 11) states, "it is well known to all that merchants sell their goods and merchandize on credit . . . and also that servants and apprentices of such merchants [sell on credit] the goods and merchandise of their lords to other men in the same way" (parenthetic in original).

Merchants had incentives to live up to contractual promises and behave as expected because information spread rapidly throughout interdependent merchant communities (Face 1958; Milgrom et al. 1990; Grief 2006). Therefore, reputations for honesty became valuable, and the threat of spontaneous, uncoordinated but effective punishment for misbehavior developed: ostracism by merchants as they received information about dishonesty (Greif 2006, 66–69).

Disputes

Deterrence is never perfect, so opportunistic breaches no doubt occurred. A merchant might accuse another of misbehavior, however, and the accused might deny it. Disputes also could arise because parties disagreed about what rule applied or how to deal with an unanticipated contingency. Impartial third-party dispute resolution reduced costs of disagreements (i.e., violence) and therefore, encouraged contracting. Merchants included arbitration clauses in contracts (Face 1959, 243), and reputable merchants served as arbitrators (Malynes 1622 [1686], 447–454). Few documents from arbitrated disputes survive, however, in part because merchant arbitrators had a "determinate power to make an end of controversies in general terms, without declaration of particulars"

(Malynes 1622 [1686], 450). Merchants wanted quick solutions to disputes so they chose arbitrators with “skill and knowledge of the Customs of Merchants, which always does intend expedition” (Malynes 1622 [1686], 450).

Temporary participatory courts, often called *Piepoudre* or Pie Powder courts, were also established at fairs. Groups of merchants traveling to a fair generally chose captains or consuls to perform various administrative duties such as determining locations of merchant stalls, but they also served on the fair court (Bewes 1923, 14). As with arbitrators, Pie Powder courts did not leave significant records: their purpose was to provide quick and equitable dispute resolution so merchants could complete transactions at one fair and quickly move to the next. Indeed, Pie Powder court rulings were not binding on any merchant other than the parties in the disputes and then only for the terms of their contracts. Decisions from different merchant courts could be inconsistent, as local rules were understood to apply in a market or fair. In fact, merchants did not have to use Pie Powder courts. Other legal systems were evolving (Berman 1983) and if a nonmerchant court with a reputation for fair decisions was willing to try a case quickly, merchants certainly could and did use it. Ecclesiastical courts were often available, for instance, because many fairs were held at priories and abbeys. Furthermore, the Church was a major producer and trader so ecclesiastical commercial rules often were consistent with *Lex Mercatoria*.

Some Pie Powder courts were taken over by authorities such as “a mayor of a corporate town. Sometimes they belonged to a lord” (Holdsworth 1903: 331). Even when a manor or urban court claimed jurisdiction, however, merchants often dominated dispute resolution (Basile 1998 [c. 1280]: 20). For instant, a lord might impose his court on a fair but use merchant juries. Some local authorities also imposed some of their own rules, but the ability to do so depended on availability of other potential courts (e.g., arbitration) and trading locations. An authority with a particularly attractive fair location could capture location rents through his court. Kings often “granted” rights to hold fairs, however, and in doing so, they

frequently stated that merchant law must apply. These grants may have deterred local powers from interfering with markets. While merchant “justice during the fairs” often was recognized by royal authority, it should not be inferred that royal “backing” was necessary for *Lex Mercatoria* when it was not threatened by a coercive power.

Universal and Polycentric Law

The medieval Law Merchant was polycentric (Benson 1999, 2011, 2014a, 2014b), with parallel, interdependent, and overlapping merchant communities using their own rules and procedures, but this does not mean that the most important principles of *Lex Mercatoria* were not universal (Epstein 2004, 8–9). Indeed, even though variations in rules over time and space were common, “the law, in its broad lines, as laid down by the merchants . . . was necessarily of the international character” (Bewes 1923, 299). By 1200 merchant behavior in commercialized Europe implies recognition of universal rules such as (Benson 2011, 2014a, 2014b):

1. Respect other merchants’ property rights.
2. Respect freedom of contract.
3. Be honest.
4. Do what you promised to do in a valid agreement, unless a subsequent voluntarily agreement alters the first contract.
5. Provide truthful information about observed misbehavior of other merchants
6. Follow local practices and usage unless all parties agree to behave otherwise.
7. Provide accurate information to foreign merchants about relevant local practices and usage.
8. Treat all merchants at a fair or market equitably.
9. If a dispute cannot be resolved, call upon an arbitrator(s) or judge(s) who is either agreed to by both parties or chosen by the relevant group of merchants [e.g., those attending a fair]
10. Accept a reputable arbitrator(s) or judge(s) who is knowledgeable about the relevant customs, practices and usage.

11. Abide by the resolution proposed by an arbitrator(s) or judge(s) within the confines of the contract generating the dispute; the same dispute is not to be taken [appealed] to another adjudicator.
12. The terms of a particular contract and the resolution of a particular dispute do not impose rules that must be followed in future interactions.
13. Support reputable members of your community [guild, caravan, ethnic or national group] if called upon to protect property or assist in pursuit and collection,
14. Provide financial support to reputable merchants from your community, and if you receive such a surety loan, repay it in a timely fashion.

There probably were other universal rules, and the importance of some rules probably varied over time and space. Significantly, however, by accepting these kinds of fundamental general rules, many more specific behavioral requirements could be generated through negotiation and contracting, and observation and emulation of effective rules and procedures meant that over time different communities evolved in similar ways.

Custom Versus Authority

When most trade took place at temporary fairs, incentives for local powers to try to control commerce were relatively weak. However, as trade expanded, permanent market towns developed. Kings often “granted” legal authority to politically important urban governments just as they did for other local authorities. Market towns were governed by local merchant and craft guilds so many *Lex Mercatoria* rules were adopted in urban law. When coercive power is established, however, discriminatory rules can be imposed (Benson 1999, 2011, 2014a, 2014b). Many urban governments began discriminating against some foreign merchants while simultaneously granting others special privileges in exchange for similar privileges in the towns where those

merchants were based (Holdsworth 1903, 302). Thus, as Coquillette (1987, note 21) explains, “surviving correspondence forms between one fair court and another, even fair courts of different countries, show a formula that clearly distinguishes between the law merchant . . . and the town customs.” Kings also extracted revenues or political benefits from commerce by imposing Royal Law (Trakman 1983; Benson 1989). Thus, *Lex Mercatoria* was absorbed and changed in varying degrees over time and space. Nonetheless, it continues to apply within many trade associations (Benson 1995) and in most international trade (Trakman 1983; Benson 1999, 2014b).

Lex Talionis

Mark D. White

Department of Philosophy, College of Staten Island/CUNY, Staten Island, NY, USA

Definition

The classical formulation of the view that the guilty must be punished in exact proportionate to their crimes: “an eye for an eye, a tooth for a tooth.”

The *lex talionis* is otherwise known as the view that punishment for crimes must exact “an eye for an eye, a tooth for a tooth.” It dates at least to the law of Moses and the Code of Hammurabi, and the general idea is cited in modern times by both scholars and laypeople in support of punishment that “fits the crime.” The *lex talionis* is sometimes used as a justification of *retributivist punishment*, which requires that the guilty receive their due punishment as a matter of right or justice, although it is less of a justification and more of a statement of the proper target of punishment (the guilty) and degree of punishment (proportionality).

The *lex talionis* is cited by key retributivists, including its leading proponent, Immanuel Kant, who asked “what kind and what amount of punishment is it that public justice makes its principle and measure? None other than the principle of equality. . . . Accordingly, whatever undeserved evil you inflict upon another within the people, that you inflict upon yourself. . . . But only the *law of retribution (ius talionis)*. . . can specify definitely the quality and the quantity of punishment”

(1797, p. 332). However, as modern retributivists and their critics alike realize – and as asserted definitively by Blackstone (1765–1769, bk 4, Chap. 1) – exact proportionality is either inhumane (such as in the case of rape), impossible (the case of multiple murders), or nonsensical (the case of attempted crime). Kant acknowledged this, asking “but what is to be done in the case of crimes that cannot be punished by a return for them because this would be either impossible or itself a punishable crime against *humanity* as such?” and moderated the *lex talionis* to prescribe instead that “what is done to [the wrongdoer] in accordance with penal law is what he has perpetrated on others, if not in terms of its letter at least in terms of its spirit” (1797, p. 363). Appropriately, it is the spirit of the *lex talionis* rather than its letter that has survived on in the form of modern retributivism, which emphasizes proportionality while recognizing its difficulties (Davis 1983, 1986).

The call for proportionality embodied in the *lex talionis* is often invoked against systems of punishment, such as deterrence, which focus on generating social benefits from punishment instead of enforcing the just deserts of the guilty. While optimally deterrent punishments – such as those recommended by the economic approach to crime – result in some degree of proportionality between crimes to create optimal incentives, they can also be disproportionately severe to compensate for high enforcement costs (Becker 1968). However, those who raise the *lex talionis* in argument are usually less concerned with disproportionately high punishment and more with disproportionately *low* ones, such as those resulting from plea bargains or judicial acts of mercy – the first of which can be justified as a regrettable compromise in the face of resource constraints (Cahill 2007) while the second is consistent with retributivism in general (Holtman 2009). At its worse, it can be used – incorrectly – to justify private acts of vengeance and “vigilante justice,” which are distinct from state-sponsored punishment (Nozick 1981, pp. 366–368; Brooks 2012, pp. 16–18). Since more refined accounts of retributivism are available that acknowledge the subtleties of

punishment in both theory and practice, the *lex talionis* is rarely invoked in scholarly debate today.

Liability and Information

Florian Baumann¹ and Tim Friehe²

¹Center for Advanced Studies in Law and Economics (CASTLE), University of Bonn, Bonn, Germany

²Public Economics Group, Philipps-University Marburg, Marburg, Germany

Abstract

The allocation of information is of paramount importance for the efficacy of liability law as an instrument to address externalities. This entry discusses several possible repercussions of imperfect information, such as inefficient

caretaking resulting from the injurer's imperfect information about the standard of care under negligence or distorted decisions about buying liability insurance. In addition, the contribution presents results from the literature on the incentives to acquire information about risk induced by liability law. Decision makers usually have the opportunity to improve their state of knowledge at a cost, and liability law will impact on the incentives to actually do so and to possibly share this information. Starting from Shavell (1992), we discuss – *inter alia* – literature analyzing the incentive for accurate harm assessment and the use of hindsight information in court, the effects of disclosure rules, or adjustments in due-care standards to further the generation of information in a process of learning-by-doing.

Introduction

The availability of information about risks is critical to the performance of liability rules in terms of inducing the efficient outcome. In this entry, we first describe certain repercussions of taking imperfect information as given. In order to provide a full understanding of the functionality of liability rules, we also discuss the incentives that such rules create with regard to the acquisition of information – that is, we consider information allocation as an endogenous outcome that can be influenced by liability rules. This entry presents results from selected works in this field.

Liability and Exogenous Information

The repercussions of taking imperfect information as given have been described for a wide range of important aspects in the context of liability. For example, erroneous assessments of harm by the court *ex post* that can be anticipated by the tortfeasor *ex ante* necessarily distort both care and activity incentives under strict liability and may also do so under negligence (e.g., Endres 1989). In the case of negligence, the choice and communication of the due-care standard are

important variables. In order to set the appropriate standard of care and to be able to compare actual care with the standard, the court needs to know all aspects relevant to the cost minimization and to observe care without error, as otherwise excessive or suboptimal caretaking may result (e.g., Craswell and Calfee 1986; Shavell 1987, Chap. 4). Moreover, when risk-averse tortfeasors are uncertain about the workings of the legal system or individual accident risk, this may affect their decision to buy liability insurance (see, e.g., Crocker and Doherty 2000; Shavell 2000). For the alternative care model, Dari-Mattiacci and Garoupa (2009) show that the least-cost avoider rule can lead to inefficient outcomes when there is imperfect information about the other party's cost of care. In the domain of product liability, how well consumers are informed about product risks is a key factor in determining which liability rule ought to be used (see, e.g., Daughety and Reinganum 2013; Miceli et al. 2015; Shavell 1987, Chap. 7). Liability rules also influence decisions about innovation and the adoption of technologies with differing characteristics in terms of the cost of care or expected harm. In this context, the policy-maker may not have all relevant information on hand (e.g., about the technologies available to firms or the level of firms' adoption costs); this means that the choice and design of the liability rule are decisive for the eventual outcome (see, e.g., Dari-Mattiacci and Franzoni 2014; Endres and Bertram 2006). In practice, when courts lack information about the relevant accident technology, they may refer to industry custom as the relevant negligence standard, potentially hindering innovation and favoring the replication of established technologies (Parchomosky and Stein 2008). For many innovations, the lack of experience will make it impossible to arrive at a reasonable estimate of the accident probability, which could, *inter alia*, undermine the insurability of risks (Skogh 1998).

Liability and Endogenous Information

The assumption that imperfect information is inevitable disregards an important factor in the

incentive effects of liability rules. Shavell (1992) provides a seminal contribution on the influence of different liability rules on the injurer's incentives to acquire information about risk and on whether they are aligned with social incentives. In his setting, information about whether or not the activity in question is risky can be acquired at a positive fixed cost. The social incentives to acquire information about risk depend on a comparison of the social value of information (stemming from the expected adjustment of care away from the level that is optimal based solely on expectations about the riskiness of the activity) and the social cost of information. When considering the performance of liability rules, Shavell (1992) employs the common assumptions that injurers are risk neutral, that the level of damage is equal to the level of harm, and that there are no issues regarding the establishment of causation. In such a scenario, strict liability results in the perfect alignment of private and social incentives to acquire information about risk, since the injurer's cost minimization problem is the same as that of the planner. For negligence, various versions of the liability rule may apply, as different behavioral dimensions may be included in the negligence standard. A comprehensive negligence rule – that is, one that holds injurers liable (a) when they did not obtain information even though it was socially desirable to do so or (b) when they did not exercise the level of care that minimizes social costs contingent on the socially optimal level of information – will induce the socially optimal outcome. Importantly, Shavell (1992) establishes that a negligence rule that uses only criterion (b) for the level of care also induces socially optimal choices by the injurer with regard to both care and information acquisition, demonstrating that one standard of behavior suffices for efficient incentives under negligence in his setup. In fact, the private value of information exceeds the social value of information, as a tortfeasor completely avoids paying the level of harm by being nonnegligent in the risky state. However, other due-care standards – namely, (i) the level of care that is optimal given the injurer's information or (ii) the level of care that is optimal when information is obtained – cannot align private and

social incentives. Standard (i) provides insufficient incentives to obtain information about risk because the injurer can avoid any liability by choosing the appropriate care in view of expectations about the riskiness of the activity; standard (ii) may also lead to inadequate information acquisition and to inefficient care.

Bajtelsmit and Thistle (2015) extend the results of Shavell (1992) by considering risk-averse tortfeasors in a framework in which liability insurance is provided by perfectly competitive insurance companies. Insurance premiums can be contingent on the observable level of care and the injurers' information about the riskiness of their activity, implying that insurance premiums match expected harm as a function of care. Bajtelsmit and Thistle find that the resulting classification risk entails a significant cost of acquiring information about the activity's riskiness, potentially encouraging individuals to avoid becoming informed; it may also render the social value of information negative. This classification risk means that injurers who acquire information about risk may discover that their expected harm is either high or low, such that information acquisition is associated with an uninsurable lottery; the alternative of remaining uninformed and acting according to the *ex ante* expectation about risk precludes any variation in income. As is true in Shavell (1992), injurers' incentives to acquire information about risk are aligned with social incentives under strict liability, whereas the results for negligence are more complex.

Kaplow and Shavell (1996) explore the social justification for the accurate measurement of harm in court; this is often a key issue in litigation and is in all likelihood responsible for a significant share of litigation expenditures. As implied by the social value of information formulated in Shavell (1992), the accurate measurement of harm *ex post* may be socially valuable only when the information can be anticipated *ex ante*. Only in this case will an injurer be subject to strict liability increase (decrease) the level of care – relative to the benchmark level without information acquisition – in states in which the expected harm exceeds (falls below) the average expected harm. By implication, acquiring information

about the level of harm in court is not socially valuable when the injurer cannot or should not obtain such information before making the choice about the level of care. Significantly, the court's decision of whether or not to accurately assess the level of harm is relevant for injurers' decisions about the acquisition of information *ex ante*.

Related to Kaplow and Shavell (1996), Ben-Shahar (1998) explores the implications of using information about the harmfulness of products that was not available when the product was marketed in the court's assessment of producer liability *ex post*. The analysis focuses on how the use of hindsight information (in comparison to a state-of-the-art approach) alters incentives for safety investments before and after the product's release, incentives for developing new technologies, and incentives to become better informed about product risks *ex ante*. The author finds, *inter alia*, that hindsight increases incentives for remedial actions after product release but distorts *ex ante* safety decisions. The impact of hindsight on the incentive to invest in new technologies is ambiguous; generally speaking, neither a state-of-the-art regime nor a regime based on hindsight results in first-best decisions regarding the acquisition of information. For environmental law, Wagner (2004) argues that it actually weakens incentives to acquire information about product risk and instead motivates attempts to discredit public research on the matter, as the information is likely to be used in support of additional regulations or standards.

In Polinsky and Shavell (2012), firms with different products and heterogeneous information acquisition costs choose whether or not to obtain information about their product risks and – contingent on having obtained that information – whether or not to truthfully transmit it to consumers. Such information may be socially valuable because it allows consumers with heterogeneous consumption benefits to make informed choices. The policy issue analyzed is whether forcing firms to reveal any information they possess (i.e., mandatory disclosure) is socially preferable to leaving disclosure decisions to firms (i.e., voluntary disclosure). Because information costs are considered private information,

the regulation of the acquisition of information is not included in the model (unlike Shavell 1992). Under the assumption that the firm's level of care must be decided before information about risk can be obtained, the authors show that mandatory and voluntary disclosure of product risks are equivalent under strict liability (as consumers' choices are not responsive to information in the case of complete compensation). In contrast, under negligence, incentives to acquire information are greater under voluntary disclosure, but the actual disclosure choice made given the information acquired is more desirable under mandatory disclosure.

Baumann and Friehe (2016) depart from Shavell (1992) by assuming that information about risk can only be acquired via learning-by-doing. In their two-period framework, the policy-maker has a prior about the true accident technology (i.e., the level of risk and how it responds to care) and uses the accident history in the first period to update the assessment of the accident technology in the second period. In this setup, because the signaling value of the accident history depends on care, the level of care taken in the first period plays a role in both the minimization of social costs and the acquisition of information about the accident technology. Accordingly, optimal care in the first period may deviate from the level that minimizes the sum of care and expected harm costs. There are circumstances in which strict liability and negligence both fail to induce the socially optimal level of care in the first period.

The idea of learning from an accident history is also explored in Feess and Wohlschlegel (2006). In their setup, some injurers know the true accident technology, whereas other injurers and the courts may be uninformed; moreover, actual injurer care is erroneously reconstructed by the court. Under these circumstances, the court will use actual injurer care as an informative signal about the true accident technology and will dynamically adjust the due-care standard accordingly. The planner thus transmits a better understanding of the accident technology (obtained from observed levels of care in negligence trials) to the uninformed injurers by adjusting the due level of care.

Most of the literature in law and economics uses the standard assumptions of rational choice theory – for example, that risk-averse subjects maximize expected utility and that future utility is incorporated using exponential discounting. Behavioral aspects may introduce other distortions with regard to what constitutes privately optimal information acquisition. For example, Chemarin and Orset (2011) discuss whether present-biased agents may acquire less information about risk than individuals with time-consistent preferences.

Libertarian Paternalism

Samuel Ferey

CNRS, BETA, University of Lorraine, Nancy, France

Definition

In their famous book *Nudge*, published in 2008, Thaler and Sunstein popularize libertarian paternalism, one of the normative theories inspired by behavioral economics. Contrary to a large tradition in moral and political philosophy that dates back to John Stuart Mill, Sunstein and Thaler can see no inconsistency between paternalism and liberalism. We discuss this statement, and we illustrate libertarian paternalistic policies. Then, we deal with the descriptive, prescriptive, and normative consequences of libertarian paternalism for the law. Last, some of the main criticisms against libertarian paternalism are discussed.

Libertarian Paternalism and the Law: Taking Cognitive Bias Seriously

In an executive order dated September 15, 2015, and entitled “Using Behavioral Science Insights to Better Serve The American People,” American executive

departments and agencies “are encouraged to [...] design public policies in line with the findings of behavioral academic theoretical and applied literature.” And the executive order refers explicitly to one of the famous libertarian paternalistic nudges, the “automatic enrollment and automatic escalation in retirement savings plans.”

Initiated at the beginning of the 2000s in several papers (Sunstein and Thaler 2003a, b), libertarian paternalism has been popularized by the famous book *Nudge* published in 2008 by Thaler and Sunstein (2008). In less than 15 years, libertarian paternalism has developed a large body of theoretical, applied, and experimental findings covering many fields of public policies (health, insurance, finance, fight against poverty, etc.) and became one of the inspiring thoughts for regulators and legislative bodies throughout the world.

The originality of libertarian paternalism relies on its constitutive so-called oxymoron: a normative theory according to which paternalism and liberalism are not contradictory anymore. For libertarian paternalism, the famous John Stuart Mill’s warnings stating that “the only purpose for which power can be rightfully exercised over any member of a civilized community, against his will, is to prevent harm to others. His own good, either physical or moral, is not a sufficient warrant. He cannot rightfully be compelled to do or forbear because it will be better for him to do so” (Mill 1869) are challenged by the recent findings of behavioral economics.

Thanks to behavioral economics, scientists and regulators know better the ways people respond to laws and regulation; they are aware of the bias people suffer, of their cognitive limitations, and of the weakness of their willpower. And the law should take people for who they are and be sensitive to the ways in which they depart from rational action theory predictions.

Libertarian Paternalism and Behavioral Economics

Libertarian paternalism elaborates on hypothesis, ideas, and methods raised in behavioral

economics. First, people are humans, not econs. They are not fully rational, coherent, and optimizers. On the contrary, they make systematic mistakes, do not perfectly learn, and are bad – at least compared to the fully rational agent ideal – at assessing probabilities, events, or any other unknown facts (Thaler and Sunstein 2008). Kahneman used to employing a metaphor: mind is led by two systems, system 1 and system 2. System 1 “operates automatically and quickly, with little or no effort and no sense of voluntary control.” System 2 “allocates attention to the effortful mental activities that demand it, including complex computations. The operations of System 2 are often associated with the subjective experience of agency, choice, and concentration” (Kahneman 2011). Explaining how the two-level process works and interacts with the environment is the basic agenda of behavioral sciences.

For Kahneman, Tversky, Thaler, and many others, it is possible to capture the process of system 1 and to display behavioral anomalies by using new empirical methods like laboratory and field experiments. Consequently, the scope of behavioral analysis for economics is to explain the ways people depart from rationality – the *bias* – and to draw the “maps” of bounded rationality. Among the main bias identified, overconfidence, loss aversion, status quo bias, anchoring, and representativeness are the most popular.

From Debiasing to Libertarian Paternalism

These new findings on how people actually behave have two normative consequences. First is debiasing: legal norms, laws, and regulations are expected to enhance individual rationality and to remove or to alleviate rationality failures. Second is libertarian paternalism. Rationality failures and bias are used to enhance people welfare. As Thaler and Benartzi state “Libertarian paternalism is a philosophy that advocates designing institutions that help people make better decisions but do not impinge on their freedom to choose. Automatic enrollment is a good example of libertarian

paternalism” (Thaler and Benartzi 2004). A benevolent policy maker, who is aware of the bias suffered by individuals, could decide to implement laws and policies which softly induce people to behave in lines with their true preferences. Under libertarian paternalistic institutions, systematic errors from system 1 are the best servant of system 2.

Let’s consider the previous example of automatic enrollment, and let’s take seriously that people suffer a status quo bias. Imagine two contexts (context 1, option A is chosen by default; context 2, option B is chosen by default). Last, suppose there is no economic or financial cost to change the initial option. In that case, because of the bias, people are more likely to choose the default option than the other. Such a mechanism is meaningful in a world where rationality is bounded. Because of the bias, the choice architect – the one who draws the default option – is able to induce people to behave in a certain way. The main issue of libertarian paternalism is to know how such a framing could be made. For Thaler and Sunstein, the choice architect should systematically select the default option which is in line with the best preferences of people: the automatic processes of system 1 are used to increase the savings, that is, what the long-term self (the far-sighted self) would have chosen. And this effect emerges without any intrusive policies and without depriving people of their rights and liberties: people stay free to choose any of the options. Here is the heart of the libertarian paternalist doctrine – also called *nudging* even though all nudges are not libertarian paternalistic (Mongin and Cozic 2017).

Libertarian Paternalism for the Law

A lot of nudges may be found in our daily life. One of the reasons why the eponymous book *Nudge* has been so popular lies in the examples provided by Thaler and Sunstein: the strives on a highway which induce people to operate the brakes before starting a dangerous turn, the alarm clock “clocky” that “runs away and hides

you if you don’t get out of bed” to struggle against lack of willpower, the default rule about your presumed consent for organ donation, etc. All these mechanisms have in common to use a bias in order to better achieve individuals’ true preferences. And legal and institutional nudges are of particular interest.

Regarding legal issues, three meanings of libertarian paternalism may be distinguished. First is a purely descriptive meaning. Libertarian paternalism makes sense of many existing legal provisions that would be meaningless if they were analyzed through the glasses of rational action theory: the cooling-off periods and delays in consumer law that protect people against their impulsive choices, the default rules that use inertia to better serve long-term self-interests, the legal framing that displays information by using salience bias, the legal self-constraints, etc.

Second, libertarian paternalism has a normative scope by offering a toolbox for new laws and public policy recommendations testable by experiments (Shafir 2012). For example, the randomized experiments designed by J-Pal experts (Poverty Action Lab) testing the best ways to struggle against poverty are sometimes explicitly driven by libertarian paternalistic views (Banerjee and Duflo 2011).

Third, libertarian paternalism is helpful to better understand adjudications by courts. This is becoming more important as more courts refer implicitly or explicitly to behavioral arguments. For example, in the famous antitrust case *Microsoft vs. Commission*, the European Court of First Instance extensively discusses the default rule and eventually considers that it is in the best interests of consumer to have a set of default options without Windows Media Player.

Is Libertarian Paternalism a New Paradigm for Law and Economics?

Libertarian paternalism is said to be a syncretic normative theory that liberals as well as conservatives could support. However, many criticisms

have raised. First, policy makers, legislators, and judges following libertarian paternalistic recommendations are assumed to be benevolent. What happens if they are not? Using behavioral sciences would give expertise in manipulation to public agents and contradict the neutrality of the State. Manipulation threatens individual autonomy, and paternalistic views threaten liberalism. Second, policy makers themselves suffer bias and are perhaps less competent than expected. One of the most important results of behavioral science is precisely to warn experts against their overconfidence and their illusion of validity and to show how experts' judgments may depart from rationality. Third, it is argued that market is able to deal with cognitive bias (Sugden 2008). But this point about the spontaneous debiasing of people by the market is still disputable in the empirical and theoretical literature (Gabaix and Laibson 2006).

These criticisms lead Sunstein to be more specific about political, ethical, and economic justifications of libertarian paternalism (see Sunstein 2014, 2015). Three arguments are of particular interest for the law. First, the choice architecture is inevitable. Any legal system offers choices under a specific frame. In that case, why not choosing the best frame for individuals? The argument is sound and convincing. Second, the threat of manipulation does not undermine libertarian paternalism as soon as libertarian paternalistic policies are under constant public scrutiny. According to Sunstein, transparency and democratic control are sufficient to avoid manipulative nudges. Third, libertarian paternalism could be considered as a set of devices enhancing autonomy because "we might identify autonomy with people's reflective judgements, and many nudges operate in the interest of autonomy, so understood" (Sunstein in Alemanno and Sibony 2015; Sunstein 2015).

To conclude, libertarian paternalism offers new smart insights on the role of the law in the economic system. But some further developments have to be made to know whether libertarian paternalism could be a general theory of the law and regulation.

Abstract

Freedom is the power to do what I want to do. The laws of nature and/or human laws limit this power. The laws of nature impose necessities. I cannot choose the speed of my fall (law of gravitation). Here I cannot have a physical meaning. Human laws limit also my power to choose, but in another meaning. They impose obligations. The law of adultery, for instance, forbids to have sexual relationships with its children. I must not in a moral sense. I do not have the right. So, human laws determine artificially the limits of my power to choose. They limit the infinite freedom of the will and leads to the study of conditions of concrete freedom possessed by human beings in society. Concrete freedom is limited by the will of others and expressed through law partially originates in a process of mutual recognition. Then, concrete freedom is based on consent.

Synonyms

Freedom

Definition

Freedom is “the power to do what I want to do.”

Liberty, Laws of Nature and Human Laws

Freedom puts the question to the relationship between human beings and nature by means of a question concerning determinism and, similarly with the relationship between one human being

and another, by means of a question concerning duty or obligation. The response of human beings to the constraint that nature places upon the will is exemplified in technology. The response of human beings to the constraints that can be imposed by other human beings is exemplified by law.

What Is a Free Action?

In order to understand why the notion of freedom or liberty involves such questioning, we must look at our experience of action and the distinction freedom makes between an action performed under constraint and a free action. Freedom is the power to choose what action one carries out. Freedom characterizes a type of action. Fundamentally, a free action is something done that could have been done in a different way. It is distinguished from a reflex action. Let's take an example. I can close my eyes in order to avoid something thrown in my direction. I can open my eyes in order to admire a landscape. When I open my eyes for that purpose, I make a choice. However, when I close my eyes to keep from getting hit in the eye by something thrown at me, the movement of my eyelids, i.e., the change in the initial situation in this case, is not the result of a choice. I never had to form the intention of closing my eyes, but my body is so constituted that it reacts automatically to the approach of such a projectile, and my eyelids close. Even if I had wanted to keep from closing my eyes, I would not have been able to prevent them from reacting, because the movement of my eyelids is determined by the way my body's nervous system works. The other situation, in which I open my eyes to admire a landscape, is different. My eyes open because I decide to open them. I decide to open them because I have good reasons to want to do so. The movement of my eyelids in reaction to the approach of a projectile is not a free act. To the contrary, the movement of my eyelids when I open them in order to admire a landscape is indeed motivated by the desire to admire the landscape. Thus, this is the description of an action that is experienced as conscious and as free. At

this point we can affirm that a free act or action has three characteristics: it is intentional (an act of will), it comes with a justification in the form of reasons for acting or motives (one wishes to enjoy looking at a landscape), and it is not the determinate result of some other act or action. This definition views human beings as responsible for their actions without requiring that actions all succeed in their purpose. Not all intentions are carried out.

Each of the three characteristics of free action calls for further explanation. Free actions are intentional. I open my eyes because I have the intention of admiring the landscape. My action is limited to carrying out this intention. My project, what I intend, is the “why” of me opening my eyes. In this sense an intention is part and parcel of reasons that justify or explain an action. Reasons for acting or motives for action are talked about in this explanation, instead of causes. An approaching projectile causes my eyelids to close together, but the beauty of the landscape is a motive or reason for my action, and not a cause. If we were speaking of final causes, beauty was the ultimate cause of my action. I can give myself a teleological explanation of the fact that I open my eyes to admire the landscape, but I give myself a physical (and *ex post facto*) explanation of the fact that I may be forced to shut my eyes in order to protect them from an approaching projectile. After the fact, I take note of the fact that something was flying toward my eye, which explains me flinching and closing my eyelids together. The explanation of a forced or determinate action is not like the explanation of a freely performed action. In one case a physical force moves a physical body. In the other case, a physical action that could not have been physically predicted is actually freely executed or motivated by a mental intention, which is further mediated by a predilection toward beauty. In the latter case, the free action is a cause of movement; in the former case, physical motion is the consequence of an external force. The cause of movement is the projectile, not the intention (Cowan 1994). The explanation of a reflex action is always *ex post facto*. I must have observed that something was going to hit my eye, and this caused me to react. The explanation of a free act is always *ex*

ante. I justify my decision to look at the landscape *ex ante*, with reference to my taste in landscapes.

The difference between a physical (instrumental) cause and a teleological (final) cause indicates the singular nature of free actions. Free action is an action that has its own cause; it determines itself. The result of this is that one may impute an action to a person or assign responsibility for the action to its “author.” This is the origin of the concept of free will as developed by Saint Augustine (Augustine of Hippo) in his treatise *De libero arbitrio*. God is not responsible for evil; human beings are, since “*Dieu a conféré à sa créature, avec le libre arbitre, la capacité de mal agir et par-là même, la responsabilité du péché*” (*De libero arbitrio*, I, 16, 35). In this regard, the will is what makes an action one's own, placing the burden of responsibility on the one performing the action (*De Libero Arbitrio* I.11). Human beings, on another hand, are not responsible for their eyes shutting when a projectile appears to be heading toward their heads. They are responsible for the act of opening their eyes to look at the landscape. In this sense, a free action involves the individual as moral person, the one who is able to respond by saying, I am the one who did this or that action. The individual is the subject who chooses or decides to look at the landscape. Freedom makes human beings into actors; they are not like stones, which cannot act but only be acted upon (Voltaire 1987, Chapitre 13, tome 62, p. 44). Voltaire makes use of Locke's theory of freedom. Freedom here is synonymous with power. This concept is distinguished from the freedom of the free will, which only has to do with the power of self-determination. A moral action is free if its consequences can be imputed to the person who chooses to do it. Inversely, an action under constraint makes human beings into objects that are acted on by forces they do not control.

In neither case is the success of the action guaranteed. Though my eyes shut reflexively, they may still be damaged by the projectile; the landscape I open my eyes is not guaranteed to be beautiful. Freedom does not protect individuals against errors in judgment that may involve the means chosen to carry out one's projects, in order to fulfill one's intentions. And the errors

committed in the one and the other case are quite different. I would not blame my own reflexes if something flew up and damaged my eye, but rather my own carelessness, or perhaps mere accident; the manner in which my body reflexively moves to avoid an external threat is not a matter of my free choice. It is a given. But a human actor can modify either a project or the means he or she mobilizes to realize the project, following an initial failure. Human beings learn from failure because they fear it. This may seem an obvious point, but it is important because it moves us away from any definition of freedom as the “maximum expansion of my personality” (Berlin 2002a, p. 179) or as itself a means for the realization of projects (Sen 1999, pp. 14–15, p. 37). Such definitions in fact confuse a free action with an action that is successfully performed or carried out. The result of a free action is not determined. This does not mean that I cannot judge freedom by its results. I can, for example, try to find out if a free society is more prosperous than the one that is not free. But such a judgment is not a definition of freedom itself or of the conditions under which it may exist.

Under What Conditions Can a Free Action Exist?

The Absence of Determinism

Regarding free action, as we have just characterized it: it is not immediately certain that it exists in reality. Human existence confirms intentionality, the existence of reasons for acting, the feeling of responsibility, and the possibility of failure. But it is not certain that the act of will that led me to open my eyes upon a landscape was not itself determined by some characteristics of the environment (of the action). Perhaps my reasons for acting or my motives in acting were after all determined by my conditions of existence. If I am not the master of my own actions, my acts are constrained in the sense that they have been determined by the conditions of my existence. Thus, human beings and their actions become again objects of nature, not subjects.

As an object, human action has the same status as a rock, a plant, or an animal. It is determined by the conditions of our existence as living beings. Genes have a desire to reproduce themselves (the law of egoistic genes, to sociobiological determinism of (Dawkins 1976)), human beings have physical needs (sleep, nutrition, etc., indicating physiological determinism), there is a law of natural selection operating (the social Darwinism of Herbert Spencer), the law of egoism or the maximization of utility (social physics), the nature of soils and climates (geographical determinism, Montesquieu, 3^e partie, Livre XIV, chap. X.; Diamond 1997), laws of the unconscious (psychological determinism, Plato and Freud), income levels (economic determinism or materialism), and/or membership in a social class (historical determinism). The free action would thus be an illusion, because the conditions of its being accomplished are not all present. This illusion stems from the fact that human beings are conscious of their actions, but not of the causes that determine that they will act. Thus, the only freedom human beings have is that they can know that they have acted in accordance with the necessity associated with their nature (Spinoza *Ethica* IV, Proposition 68). Freedom would be the recognition of necessity (Berlin 2002b, Chapitre Hegel). If I want to build an airplane, it would be suicidal to attempt to violate any of the laws of aerodynamics. Fatalism is the moral (prescriptive) consequence of this definition of freedom which associates determinism and freedom as the recognition of necessity.

Applied to the institutions of human societies, to morality and law, this may mean that human beings are able to want to change their society's institutions, but there is a natural order which is imposed on human beings by institutions. Human beings may desire to change their institutions and not be able to do it. They find themselves in the position of someone who would like to alter the speed at which he is falling. The universal law of gravitation discovered by Isaac Newton states that two bodies in the universe attract each other with a force that is directly proportional to the product of their masses and inversely proportional to the square of the distance between them. Human

beings do not choose the values of physical constants. In an analogous manner, all the laws of nature that are the basis of different forms of determinism (as mentioned above) place human beings in this world of necessity. The projects and intentions they conceive are always determined from outside. There is always something that motivates people to do what they do. In this sense, this position is fundamentally empirical. Reasons for acting are externally determined. There is a necessity attached even to the projects expressed in action. Freedom consists precisely in knowing this. Thus, it is only a single step, which takes us from the consciousness of our being subject to necessity, to cynicism.

The Consequences of Determinism With Regard To the Identification of the Conditions of Free Action

Freedom as the Power to Choose The first consequence of determinism is that freedom is defined as opposed to the absence of choice. I have not the choice of speed when I fall. Nor do I have the power to choose not to nourish myself or not to sleep, assuming I want to stay alive. In the world we live in, life only sustains itself by fighting against death (Boulgakov 1912, 2000, Chapter I, II). Basic needs (for sleep and food) must be satisfied; these are conditions of human beings' biological existence. Human beings are in a sense slaves to their own bodies, which have to be looked after. Staying alive is a choice that determines action. One must choose to live in order to choose a particular project of action. The project of survival is conditioned by work, labor, inasmuch as it is a condition of life from an economic point of view. Work is the result of the threat that nature poses to human beings. It is a necessity. It places human beings in a state of needfulness (poverty). This is Adam's curse. But since work allows human beings to get control of basic necessities, it is also the means of extricating oneself from it. Work is a source of redemption, not of enslavement.

The Power to Choose and Social Physics in the Economics of Institutions

The second consequence of determinism is that it leads to the denial of the existence of non-necessitating purposes ("ends," as in Aristotle), in other words the fact that things might be otherwise than they are. In the economics of law and of institutions, this turns out to have important consequences with regard to the way institutional dynamics are modeled. At first, there is a tendency on the part of the theory of cultural evolution to accept a Panglossian economics (Whitman 1998). In such perspective, which is, is rational and what is rational is efficient. In such a world, there is no place for change or for the change agent, the entrepreneur. The same discussion can take place when we apply the law of egoism or the principle of the maximization of profit in order to explain law. Without law, human beings are not at liberty to desire something other than the maximization of profit. This is a given, but not a variable. That which varies is the manner in which individuals exercise their ability to calculate, rather than the objective aimed at by the calculation. The entire art of legislation, as Helvétius had already said (Berlin 2002b, Chapitre Helvétius), is therefore *"de faire que l'individu trouve plus d'intérêt à suivre la loi qu'à la violer."* The entire contribution to the theory of inducements to the legislator is to suppose that the economist can furnish legislators with the means to predict what individuals will do if the rules of the game are changed, that is, if the incentive structure is manipulated, and the division of costs and benefits for each alternative. Such an ambition supposes that the law of egoism always applies and that altruism and disinterested acts are only illusions.

The theory of action teaches us to consider free acts as determinate acts. A free act is founded upon the existence of non-necessitating ends or purposes. Only ends of this type allow human beings to remain entirely free (Gilson 1997, p. 315). The law of gravitation cannot be broken, but human laws, moral or legal, can be involved in a choice. A human law, in fact, is obligatory without being necessary.

The Power to Choose and Nonempirical Approaches in the Economics of Institutions

Affirming the existence of non-necessitating ends

has therefore several consequences. Each of these consequences explains the originality of non-empirical approaches to the law and institutions. (1) The existence of non-necessitating ends first of all restores the determination of the self by the self. This self-determination is a characteristic of the free act. It explains why a certain number of authors insist on the absence of domination (Petit 2001, p. 132) or noninterference (Carter 1999, p. 237) in the definition of freedom. (2) The existence of non-necessitating ends also has the consequence of restoring the entrepreneur to his place as a change agent in the analysis of the dynamics of institutions. The institutional entrepreneur (Yu 2001) does not react to the evolution of constraints (transaction costs), but is at the beginning of his own movement. He acts, he does not react. (3) Non-necessitating ends also rehabilitate human beings' responsibility within history. They modify people's attitude toward reality. When I believe I am responsible for my own destiny and develop a strong feeling of personal effectiveness (*self-efficiency*), I have a tendency to become a change agent (Harper 2003). (4) More generally, the entrepreneur now has space in which to maneuver regarding all the laws that do not establish necessitating ends. If human laws, that is, morality and law, have this characteristic, then human beings can liberate themselves from laws that constrain them by refusing to apply them. They have the power to stand apart from their conditioning. They can overcome internal obstacles to freedom, such as addictive behavior (to tobacco, alcohol, coffee, morphine, opium, cocaine, sexual activity, even tyranny (de la Boétie 1549)). To be free is to be capable of subordinating one's action to the law of duty (a non-necessitating end). In this world of duty, passions and emotions no longer enslave human beings. In the face of danger, a soldier necessarily has a feeling of fear. It is his duty to fight. He must overcome his fear and refuse to flee or hide. The will allows us to overcome inner constraints. The will also allows us to go beyond external constraints, that is, we are able to choose whether or not to have recourse to the formal or informal institutions that structure the social order. These institutions limit a world of possibilities, but they

only define obligations. They are not necessary. It is always possible for people to avoid them or to disobey them (*civil disobedience*) (Thoreau 1849). (5) The last consequence of the existence of such ends is that law and moral rules are not similar to the laws of gravitation, although they claim to be as much in force. So laws that forbid stoning an adulterous woman artificially institute a necessity between two events that are not at all connected in nature. They artificially create determinations by instituting obligations. The fact that it is possible not to conform to them does not make them any less destructive of liberty. It is not because I can leave my own country to escape the oppression of a dictator or taxes that the law protects my power to choose. The word "power" changes its meaning here. In the case of the law of gravitation, "I can not" has a physical meaning. In the case of the law on adultery, "I must not" in a moral sense. I do not have the right. The law artificially determines the limits of my power to choose. It limits the infinite freedom of the will and leads to the study of the concrete freedom possessed by human beings in society (Hegel 1821, §4, §30).

Respect for the Principle of Self-Determination by the Self

The Ideal of Contractual Law

It is not only laws of nature that limit freedom. There are also human laws, morality, and the law of the courts. The origin of this limit has to do with a confrontation between two wills. The infinity of free will, that is, the possibility of willing, even the impossible becomes concrete freedom when two wills (Hegel 1821) or two individual claims (*pretesa/pretesan*, Léoni 1961) oppose each other. This explains why possession becomes property and takes on a legal character to the extent that the other, or all others, recognize that a thing I have made mine is mine, as I recognize others' possessions as their own. Concrete freedom that is expressed through law partially originates in a process of mutual recognition (Facchini 2002), the other part dealing with connections of a contractual type. Law guarantees the conditions of the free will if it is the result of that confrontation of wills, which accept the task of mutually

limiting one another all in taking account of the wills of others. Law limits the power to choose. It exercises a constraint without for all that violating the principle of self-determination by the self. This represents the fact that human beings can limit their own power to choose through laws that they freely support and which they apply thanks to the implementation of trust rules and solidarity rules (Vanberg and Buchanan 1990). These laws constitute an order based on rules (order of rules, Hayek 1973) that change as a function of the relationships between the wills of different members of a group. Concrete freedom is based on consent. Outside the contract, law becomes the death of liberty, for it is imposed against the will of human beings.

Freedom, Tyranny, and Paternalism

In the great conflict of wills, the other may also decide on a constraint for me to labor under. The law, here, is chosen against my will by another will than mine. The principle of determination of self by self is no longer being respected. Law is no longer creating the conditions necessary for the existence of a free act recognized as such by everyone. Only the one who produces the law is free. For my own happiness, he subjects me to his will (paternalism) – or if it is for his own happiness, he is a tyrant.

The tyrant has the face of a bad person in Pascal's sense (1650, 1982, p. 125). The bad person has power and uses his force to impose his will on me. The confrontation of wills no longer can be solved through contracts, but only through the application of the law of strength, of the stronger party. The stronger party will oppress the weaker (Pascal 1650, 1982, p. 127). This transforms a factual situation into a law. What the strong possess is transformed into property rights. This means that at the beginning there is no agreement about the rights of each, but there is usurpation (Pascal 1650, 1982, p. 125). The law makes the strong free and places the weak in a situation of necessity, because freedom without power is impotent. Under these conditions the infinite freedom of the will of the weak will never receive a proper concrete expression in the law. The weak can band together to overthrow the

strong and impose their own laws, but they will never be liberated unless they reverse the relationships of force, making yesterday's strong people the weak and the oppressed of yesterday the strong. The law is necessarily that of the strongest, if without force the will is powerless. The social and political conditions of a free society will never all be present. The infinite freedom of the will is therefore only an illusion, since law is always the law of the stronger. He supports the freedoms of some but oppresses the freedom of others.

The legislator can also assume the form of a benevolent father. The strong man ceases to be a tyrant. He places his power in the service of the Good. The original form of paternalism consists in helping individuals to keep their promises, that is, to make the will of the weak-willed strong. Let us suppose that a weak person does not permit himself to commit adultery, but through the weakness of his will, he succumbs to temptation just the same. Such a situation may justify intervention on the part of the strong man. His intervention will be like the chains holding Ulysses to the mast as the Sirens sing, in Homer (Elster 1984). A second form of paternalism consists in deciding on the extent of the means that individuals give themselves in order to realize their goals. A man who wishes to be in good health should not smoke. The strong person can justify constraint with reference to the incoherence of the weak person. The weak person will not be allowed to smoke, as a means of helping that person reach their personal goals. A third form of paternalism, *soft paternalism*, prohibits nothing and uses no force but tells weak or poorly informed people about the risks various behaviors are associated with. They remain free to do as they like. But they are obliged to hear out the morality of the strong. A fourth, hard paternalism, is moral. It determines the ends of action not because the strong man wants it that way, but because the good can be objectively determined. The strong man knows what is good and seeks to promote it through politics, in which the ultimate aim is the happiness of men in society (Humboldt 1851, III). In the name of this principle, this stance gives itself the freedom to act as a tyrant in the name of the Good. Thus, we have here to do with a benevolent tyrant.

The Ideal of Contractual Law and the Role of the State

The introduction of the figure of the strong person in a contest of wills is equivalent to a consideration of the role of the State in the formation of law and the protection of individual liberty (freedom).

The law that is generated by the benevolent attitude of the strong person changes as a function of the strong person's knowledge of that which is good. It establishes the strong person as a legislator and exposes society to two kinds of risk. Happiness from this perspective dominates the principle of non-domination of one individual by another. The legal conditions of a free act are not guaranteed. The law of the legislator then risks becoming unstable because it evolves as a function of what the legislator learns concerning what is to be done or not done in order to bring about the happiness of human beings in society. This instability of the law reduces the quality of what agents are able to anticipate and increases the cost of their coordination. It opens the door to higher costs for political transactions, since everyone is attempting to influence the decisions of the legislator and to impose their own conception of the Good. The law of the legislator, in addition, no longer mobilizes the group of kinds of tacit knowledge that agents have when they are constrained only on a contractual basis. The law therefore has a good chance of being poorly adapted to many particular situations and for this very non-applied reason.

The law of the tyrant serves the tyrant's will. It includes the tyrant's conceptions of the Good. Therefore, it also has an unstable, arbitrary, and incomplete nature.

The law of a contractual nature is to the contrary freely consented to and based upon the tacit knowledge of agents. It may nonetheless be unstable, because it is never certain that one of the parties to a contract may not decide at one moment or other to refuse to keep his or her promises. A person may in fact decide that he or she is in a position of strength and that it is no longer in that person's interest to continue to be bound by agreements that were freely agreed to in earlier negotiations. This risk is real. It is normally limited by

the existence of rules involving confidence and solidarity that are made specifically to prevent such behavior by instituting dissuasive mechanisms such as guilt, shame, a bad reputation, exclusion, and/or ostracism. All the individuals of the group band together against the deviant, that is, the individual who does not wish to keep his or her word. If these rules are sufficient, the State has no role. Its existence is nothing but a useless fiction through which the freedom of some people is extended to the detriment of others' freedom, that is, through which "*tout le monde s'efforce de vivre aux dépens de tout le monde*" (Bastiat 1863, Tome IV, pp. 327–341). Only when the State arrogates to itself a monopoly on violence and the production of the law (Léoni 1961) does law become the law of the strongest. If risk is not obviated through the application of these rules and mechanisms for imposing sanctions, human beings may have recourse to force, in other words may make agreements so that power ensures the maintenance of law and order. The State is a regalian State. It ensures the enforceability of contracts against external enemies and/or internal strife (Humboldt 1851, 1969, IV, p. 45). This means taxation is one condition of a free society, for it is the condition for the financing of the operations of the police and for the defense of the State's boundaries. The financing of the police from this perspective is the single issue regarding political freedom. These freedoms guarantee to the individual the power to choose his level of taxation, his rules of allocation, and the people who will manage everything.

Lies and Decision Making

Alessandro Antonietti¹, Barbara Colombo² and Claudia Rodella²

²Department of Psychology, Catholic University of the Sacred Heart, Brescia, Italy

Abstract

Within the economics and law fields, many decisions must be based on what is reported by another person, who can deceive the decision maker by lying. Thus, discovering if our interlocutor is sincere or not is crucial in order to make good decisions. Research highlighted that the spontaneous strategies that we use to identify possible lies are often misleading. Our moods and personality, together with the level of trust between speakers, are all factors that can influence the detection of lies. However, the ability to discover lies may increase with appropriate training and experience of dealing with people in contexts where the probability of being deceived is quite high. Regardless of our actual skill in discovering lies, our attitude toward lying can influence the decision-making process. For example, when we are aware of the possibility that a lie occurs, a suspicious attitude can lead to a wrong judgment. Similarly, perceiving an alleged lie, whether it is real or not, can prompt the use of

emotional heuristics linked to the perceived feelings of antipathy, anxiety, or anger. This can lead to decisions aimed at creating disadvantages for the partner. Under these circumstances, it is necessary to take into account the variety of human behavior, not relying on stereotypes to identify a lie. Being used to interact in particular contexts where the risk of being deceived is high may definitely help to sharpen the ability to find out who is lying to us, increasing the likelihood of taking rational choices based on reliable cues.

Lying in the Field of Law and Economics

Within the economics and law fields, many decisions must be based on what is reported by another person. This happens, for example, when a judge has to issue a sentence on the basis of statements made by the witnesses or when a broker has to decide to invest money by evaluating the reliability of a company on the basis of what an analyst tells him about it. In these situations, it is generally assumed that the other party is sincere. However, people may lie, for various reasons: for personal interest, to defend the interests of others, for idealistic reasons, and so on. Therefore, it becomes important to know how to identify when a person is lying and manage the decisions accordingly.

Psychological knowledge can be helpful. Although there is no “truth machine” that is able to establish with certainty when one is lying, there are research data that provide guidance in this regard. The studies which have been carried out allow us to identify what causes people to lie, which are the situations when this is more likely to happen, what are the personal characteristics that distinguish liars, and how lying may affect ethical and economic situations. Being aware of these aspects may allow one to take appropriate decisions when other people lie.

Why People Lie

Lying occurs when there is no correspondence between what one says and what he thinks,

knows, and feels. This can occur when the individual does not have full knowledge of how things really are or when his/her communication is not adequate. In these cases, the person tells a lie, but it is a falsehood due to ignorance or error. Lying, therefore, has more to do with the *truthfulness* (i.e., what the person believes to be truthful) than with the *truth* per se. We are lying, as we are discussing here, when people deliberately attempt to induce others to believe that things are different from what we believe they actually are.

All of us are aware of how we tend to lie during our everyday life. We lie for many different reasons, from the most trivial to the most important ones. Studies showed that during a normal conversation people make use of deceitful assertions in 61.5% of cases (Turner et al. 1975). In general, we tell minor or white lies, which require a limited mental commitment to be planned and communicated and do not cause excessive stress to the actor because, even if the lie is discovered, the consequences will be not heavy. In other situations, however, lying can have serious consequences on the decisions that are taken, and this happens quite often when economic or legal aspects are involved.

Despite some research supporting the notion that the number of lies told decreases with age (Jensen et al. 2004), other studies showed that lying is an essential part of communication among adults (Camden et al. 1984; DePaulo and Kashy 1998; DePaulo et al. 1996; Hample 1980; Turner et al. 1975). Actually, what changes with adulthood is the social desirability of a lie, which is less accepted as a suitable mean to achieve a goal. In addition, children are more naïve and believed to be always credible, even if their lies are less elaborated and complex. This is why it is usually much easier to discover a child lying, compared to an adult, who has many more resources and an advanced ability to lie. For this reason, we may wonder if children actually lie more or if they are simply discovered more often and have less fear of confessing.

Many theorists argued that deceitful communication is linked to survival: men used to lie to get what they needed when they were lacking of resources. Like other behaviors that are

maintained over time for this reason, lying has a different meaning today. We do not lie only to obtain the resources needed for our survival but also to obtain superfluous goods (tangible and intangible), to look better, to deceive others, to protect those we care about, and so on.

Survival is also used to explain why people believe the lies. If we had a cautious attitude toward what others say in every moment of our lives, we would run the risk of spending a lot of time and energy in order to assess the evidence of the communication of others, in order to determine the authenticity of what they are saying. People would be too suspicious, not allowing social relationships to be lived fully and peacefully.

Universally speaking, human beings tend to give credit to what others say. This trend presents two levels: on one hand, if the speaker does not have any particular reason to lie, he/she will say what he/she thinks is true; on the other hand, if the listeners do not have any particular reason to doubt the speaker, they will accept as true what the speaker communicates. These statements refer to Grice's principle of cooperation: according to this principle, you have to "make your contribution such as it is required, at the stage at which it occurs, by the accepted purpose or direction of the talk exchange in which you are engaged" (Grice 1989, p. 26). This truth bias is an important cognitive heuristic, i.e., a system that allows one to evaluate complex stimuli with a reduced cognitive commitment (Caldwell 2000). This is only one of a number of heuristics that humans commonly use. Another example can be the heuristic according to which it is easier to falsify facts than feelings: therefore it is more likely that people evaluate as false factual statements than emotional utterances.

Identifying Lies

Human beings tend to overestimate their ability to identify a false communication. In fact, decades of research have shown that humans are modest debunkers of the lies (Hartwig and Bond 2011). One main reason why humans have limited skills

in detecting lies is related to the lack of certain, absolute, and universal hints that can be used to identify lies. The second reason is related to the high level of complexity of human communication. Even when we tell the truth, we use a wide range of communication strategies. This means that when we want to lie, we just have to slightly change part of the communication configuration. As a consequence, differences between truth and falsehood are difficult to be detected. Thirdly, people have stereotypical theories on liars. Since such theories are not based on empirical evidence, it is not surprising that they can easily lead people to errors of judgment (believing that one is lying when he/she is telling the truth or thinking he/she is sincere when in fact he/she is a liar). As a last point, as mentioned above, social conventions that guide interpersonal relationships induce individuals to not have a constant suspicious and inquisitive attitude. Doubting everything and constantly accusing others of being a liar would prevent any relationship of intimacy and trust to develop.

It is interesting to note that there are some categories of people who are better able at discovering liars. This is the case of criminals, spies, secret services' employees, and those who are well trained to lie or have to deal with lies on a daily basis, as well as those whose life depends on their lying skills (Vrij and Semin 1996). Moreover, some professionals are more experienced than others, such as police officers and clinical psychologists (Ekman et al. 1999). Different studies (DePaulo 1994; DePaulo and Pfeifer 1986; Ekman and O'Sullivan 1991; Kraut and Poe 1980; McCornack and Levine 1990; Rosenthal and DePaulo 1979) reported that the experience in dealing with lies increases the confidence in the ability to identify them. This, however, does not correspond to an actual accuracy of the assessment. The only exception seems to be the American secret services (Ekman and O'Sullivan 1991). The possible influence of a deep relationship – like the one between partners, family members, or close friends – in detecting lies has also been explored. However, even in this specific case, the only variable that changes significantly is the declared level of confidence in being able to discover the lies of those who are

close to us. Yet, this does not show any positive correlation with the accuracy of the judgment (McCornack and Levine 1990). Rosenthal and DePaulo (1979) also investigated possible differences due to gender. The only significant result they reported is that men tend to be more suspicious than women, even if this does not mean that they are more skilled at exposing a lie. Toris and DePaulo (1984) conducted a study in order to verify if people were better at spotting a lie if they were notified of the possibility that they were lied to. Results showed that individuals become more suspicious, believing more people to be liars. Once again, yet, they were not more accurate in their judgments.

Starting from this evidence, we can conclude that a direct discovery of falsehood is impossible, mainly because we do not have the ability to read the minds of other people. However, we are potentially able to detect lying in an indirect way, relying on more or less reliable indices, although this ability is very complex and is usually rare to possess without a specific training. It is important to remember that no tool and no method is fool-proof and that the best procedure involves the integration of multiple systems (analysis of non-verbal behavior and of content and consistency of communication, attention to contextual and cultural cues as well as to speaker's personality, and so on). Along this line, it has been proved that even when there are clues that are sufficiently clear to detect lying, most people do not use them (O'Sullivan 2009). However, it is important to stress that a proper training can significantly increase the ability to recognize clues that are associated with lying and to discern between truthful and false discourses. Paul Ekman has been studying for many years the most relevant behavioral clues related to lying. His studies helped him in developing a program to teach people to be able to recognize the micro-expressions that, within a communication flux, provide information about how the other speaker is going to behave. The micro-expressions are particularly useful to predict threatening and/or dangerous behaviors (Ekman 2009). Micro-expressions are closely linked to emotions. Ekman himself, along with other authors, showed

that aphasic patients are particularly sensitive to these clues and this allows them to detect more accurately a lie (Etcoff et al. 2000). Emotions can challenge the liar, too: he/she may be betrayed by his/her emotions or may fail in the construction of the lie because of the influence of emotions. These two errors lead to qualitatively different behavioral indices as they are linked to different emotions: fear of being caught rather than guilt (Ekman and Frank 1993).

Deciding When Exposed to Possible Lies

We can assume that when we are facing a situation where there is the possibility that the person we are talking with is lying, we must determine whether we can trust him/her before taking any decision (Riva et al. 2014). To do this, we have to make inferences about his/her intentions. This can be done either through an immediate and holistic process or through a slower and analytical one (Iannello and Antonietti 2008). In other words, this may occur either through a rapid intuition or through a detailed and systematic examination of the person and the situation at hand. In the first case, the process resembles the formation of impression, whereas in the second case, the process involves a more logical assessment (Iannello et al. 2014). In this respect, intuition and analysis are conceived as different decision-making approaches (Stanovich and West 2000).

Slovic and colleagues (2002) have proposed a decision model based on the presence of two interacting cognitive processes: the analytical system, which is based on rules and on the decision maker's explicit control, and the intuitive system, based on impressions that arise automatically, without any special effort or intention. This system is activated immediately, together with the first reaction to a stimulus, which is often an affective reaction. In this regard, it is relevant to point out how the intuitive-affective reaction plays a key role in the perception of risk and benefit: if the people "like" a stimulus, they tend to underestimate the risks and overestimate the benefits; if they "do not like" it, they will probably assess the risk as very high and while considering

the benefits as being quite low. The process of judgment based on the affect feeling associated with the stimuli has been called by Slovic *affect heuristic* and is considered the key component of an intuitive decision.

Kahneman (1994) is another author who distinguished the choices based on emotional feeling (choosing by liking) from the comparative analysis of options typical of the normative choices (choosing by dominance). Whereas the last typology of choices considers the nature of the different options, the first one, based on the pleasantness, is mostly determined by emotional feelings associated with the alternative choices. We activate this strategy especially when lacking information to perform an effective assessment of the value of the stimulus (Hsee et al. 2005).

Some studies have shown that the individual mood may influence the decision-making process (Schwarz 2002). When we experience a negative mood, the decision-making process takes longer and is characterized by a greater attention to each attribute. When we are in a positive mood, instead, we tend to evaluate with greater shallowness, increasing the use of intuitive strategies.

An Example of a Complex Approach to Decision Making and Lying

As we have seen, when we have to take a decision while we may be deceived because our partner is lying, we tend to use both the intuitive processes (through which we try, by relying on our impressions and emotions, to understand if our partner is trustworthy) and the analytical processes (through which we examine the information we have about our partner from a rational standpoint). Personal characteristics play a major role, since they lead an individual to rely more on the former or the latter of the two kinds of processes. This specific decision-making process is therefore a complex process that requires a complex approach to be appropriately investigated. As an example of a psychological investigation of this process run by applying a complex approach, we report the case of a recent study (Colombo et al. 2013).

The experimental study of the relationships between lies and decision making requires the use of simplified tasks with respect to the daily life situations. In this specific study, a variant of the Ultimatum Game has been used. The Ultimatum Game (Powell 2003) is a task where a subject A (proposer) is given a sum of money and is asked to split it with another subject B (responder). B has the choice to accept or reject the proposed division. If the proposal is accepted, the split of the money becomes effective; if it is refused, both players receive nothing. This task involves both moral (fairness of the split) and economic (maximizing personal benefit but also reciprocity) considerations. According to the theory of rational choice, B should accept any sum A proposes, following the logic “better than nothing.” Actually, research shows that many unfair offers are declined according to the principle of aversion to inequality. B, therefore, generally does not accept an offer that falls below half the amount.

In the experiment we are discussing, the participants, playing as proposers, saw six videos where six different people (the responders), balanced by gender and age, gave information about themselves. Information sometimes was false. In addition to deciding how to split the amount of money with the different responders, subjects were asked to express an opinion on the truthfulness of what each partner said while introducing himself/herself. Each character gave the same amount of relevant (e.g., “I am person who does not compromise”) and nonrelevant (e.g., “I believe in values such as friendship and family”) information about himself/herself. Only half of the sample has been given prior information concerning the possibility that respondents may have been lying. While the subjects performed the task, eye movements were recorded using an eye tracker, a noninvasive tool that uses infrared technology to study the relationship between eye movements and information processing. Before the experiment, participants were tested to assess specific personality traits (such as impulsivity) and their preferred decision-making style (whether intuitive or analytical).

A first result concerns how people tend to consider information they receive. Participants

judged as true what partners said about themselves in the majority of cases, confirming what already reported in the literature. Another data that corroborates findings of previous research is the difficulty in identifying a false communication. The subjects failed in this task in about half the cases. The type of instructions received, however, affected the behavior. As mentioned above, half of the sample did not receive any information about the possibility that some of the respondents could lie, whereas the other half was aware of this possibility. As expected, the subjects who were aware of the possible presence of liars changed their behaviors: on one side, they seemed to be more suspicious, while on the other side, this awareness seemed to promote positive feelings toward the partner who has been considered sincere. In any case, however, knowing about the possibility of being deceived did not improve the performance in terms of accuracy of the judgment of truthfulness.

Data also showed that impulsivity activates stereotypes – as is also reported in other studies (e.g., Baldi et al. 2013) – or distracts from the search of clues of deception, leading to bid higher to the responders. More reflexive people are more meticulous and more responsive to information that they receive. In this specific experiment, this led to propose a lower sum of money to the respondents. The influence of personality seemed to result in a greater emphasis on the perception of similarity or difference with respect to respondents. When participants were able to “get into the shoes” of the respondent or somehow considered him/her similar to themselves (maybe for similar age and same gender), people adopted a more rational approach in splitting the money. From the opposite perspective, the greater the perceived distance from the responder, the greater the difficulty to make a logical decision.

Another hypothesis of this study concerned the fact that the visual behavior could be unconsciously influenced by the variables mentioned above. Data from the eye tracker highlighted that the main attentional focus was always on the “person” (eyes, mouth, face, and torso) when individuals were looking for a lie. They seemed to focus mainly on the eyes, probably because

they are considered as a point of reference to test whether the communication addressed to them is genuine or false.

Summarizing the data obtained from this study, it can be concluded that human being is by nature inclined to believe a communicational partner to be sincere and that, even if he/she is alerted about the possibility of receiving a false communication, he/she does not become more skilled or accurate in spotting a lie. Specific characteristics linked to personality and decision-making style appeared to play an important role: a greater impulsivity leads to the activation of a more automatic reasoning, diminishing the possibility of using a logical and rational thought.

In the same study, Colombo and colleagues (2013) also tried to modulate the choice through a technique of noninvasive brain stimulation, using the transcranial direct current stimulation (tDCS), which was applied on the prefrontal cortex. This area is well known for being involved in decision making. In previous studies (Antal et al. 2007; Kuo et al. 2013; Lang et al. 2004; Nitsche and Paulus 2001), it was reported that the application of this kind of stimulation is associated with a modulation of cortical excitability, which leads to an inhibition or activation of the stimulated area. The prefrontal area is specifically linked to inhibitory mechanisms (Bembich et al. 2014; Ding et al. 2014; Lee et al. 2014), so it was expected that the stimulation of this area could induce a change in the level of impulsivity and, consequently, in promoting the intuitive rather than the analytical approach (Iannello et al. 2014). Indeed the subjects, as a result of the stimulation of the prefrontal cortex, exhibited significantly different behavior. To be more specific, they seemed to become more rational. In the control (namely, no stimulation) condition, irrational behaviors emerged, like offering no money to the respondent to “punish him” for being dislikeable, not considering that acting this way they would not get anything, since the responder would obviously reject this partition. The stimulation of the prefrontal cortex, instead, led participants to rely on the relevant data supplied by the respondents, making the most of each detail.

Conclusions

Lying is something we deal with on a daily basis, even though most of the times we do not invest energy in order to discover either our interlocutor is sincere or not. Whenever we communicate with other people, sometimes we wonder if they are lying, because we are aware that lying is a characteristic of human beings. Nevertheless, the automatic and spontaneous hypotheses that we generate to assess the truthfulness of a statement are often misleading and do not lead to an accurate assessment. Our moods and personality, together with the level of trust between speakers, are all factors that can influence the detection of lies. Similarly, a careful assessment of information and how it is communicated does not guarantee the accuracy of judgment. Having said that, the ability to discover lies may increase with appropriate training and experience of dealing with people in contexts where the probability of being deceived is quite high.

In those fields – like law and economics – where the analysis of information received is critical, it is crucial to understand how the perception of lying can influence the judgment and, ultimately, the decision-making process. Regardless of the actual presence of a deceitful communication, when we are aware of the possibility that it occurs, a suspicious attitude can lead to a wrong judgment. Similarly, perceiving an alleged lie, whether it is real or not, can prompt the use of emotional heuristics linked to the perceived feelings of antipathy, anxiety, or anger. This can lead to decisions aimed at creating disadvantages for the partner. Under these circumstances, it is necessary to take into account the variety of human behavior, not relying on stereotypes to identify a lie. Being used to interact in particular contexts where the risk of being deceived is high may definitely help to sharpen the ability to find out who is lying to us, increasing the likelihood of taking rational choices based on reliable cues.

Abstract

From being a symbol of the necessity for publicly financing public goods, since Coase’s 1974 article “The lighthouse in economics” the lighthouse has instead become a symbol of the private sector’s ability to provide public goods, and subsequently an archetype of a mistaken economic policy justified by “market failures.” However, recent studies in economics, law, and history have uncovered different mixes of private and public finance in the provision of lighthouse services over time, exhibiting the practical problems involved in providing public goods.

Introduction

The lighthouse has long been cited as a locus for public intervention – at least since John Stuart

Mill (1848, p. 968), who referred to the difficulty of obtaining payments for such services. The example was taken up by Henry Sidgwick (1901, p. 406), who saw it as a free-rider problem (explained by a failure of appropriation). Arthur Cecil Pigou (1932, p. 184) reinterpreted it as a problem in which the social product is greater than the private product (nowadays called a positive externality). Paul Samuelson (1964, p. 159) cited the lighthouse as an example of external effect and public good (absence of exclusion and of rivalry). Kenneth Arrow (1969, pp. 146–147) added that even if these problems were solved, there would remain a problem of bilateral monopoly in the absence of competitive prices.

But in 1974 Ronald Coase described a system of lighthouse financing in England and Wales, from the sixteenth to the nineteenth century, in which private individuals embarked on financing, building, and maintaining numerous lighthouses, and obtained payments for this service. He thus laid claim to the lighthouse as an example of a standard, mistaken, approach in economic policy and, more generally, of economists' lack of concern for the real world. The lighthouse thus became the classic example of "the failure of market failure" (Zerbe and Mc Curdy 1999).

While widely repeated, Coase's conclusion was not totally accepted by Samuelson (who still cites the lighthouse as an example of a public good – see Samuelson and Nordhaus 2010), and it has systematically been called into question by lawyers, historians, and economists (Van Zandt 1993; Taylor 2001; Bertrand 2006): the old English system, it is argued, was neither truly private nor really efficient. This has renewed the debate over the nature and efficiency of the English lighthouse system among economists and historians (Barnett and Block 2007, 2009; Bertrand 2009; Block 2011; Carnis 2013, 2015; Lindberg 2013; Levitt 2016), and studies of other historical systems have flourished (Bertrand 2005; Lai et al. 2008a, b; Poder 2010; Lindberg 2015). This is a controversy about the different modes of financing and maintaining lighthouses that have actually existed (private, public, and other hybrid modalities) and their relative efficiency pursued in a truly Coasean spirit.

Coase and the Old Lighthouse System: A Possibility of Efficient Private Financing?

As related by Coase (1974), the history of English lighthouses is one of private entrepreneurs embarking on building and maintaining lighthouses in order to remedy public failures. Trinity House, a private charity in charge of lighthouses, was founded in 1514. At the beginning of the seventeenth century it was building very few lighthouses, and private individuals, supported by petitions from sailors and ship-owners, obtained patents from the Sovereign allowing them to build lighthouses at specific places and collect corresponding payments (and excluding others from doing so). Similarly to the lighthouses of Trinity House, these "light dues" were collected by Customs officers in harbors on a ship's arrival, and their amount depended on the route and tonnage of that ship. From 1679 onwards, Trinity House itself, having obtained a patent, could grant its right to a private individual, generally on a rental basis. During the eighteenth century, it was mainly private individuals who built lighthouses. But as early as 1820, Trinity House began to buy "private" lighthouses at the request of the House of Commons; this process was completed in 1842. The House of Commons justified the centralization in the first half of the nineteenth century by the complexity of the system and the high level of dues that went into private pockets, damaging British vessels' competitiveness.

In the old English system, Coase sees the possibility for a private entrepreneur to finance and maintain a lighthouse with financial gain as his sole motive:

The early history shows that, contrary to the belief of many economists, a lighthouse service can be provided by private enterprise. [...] The lighthouses were built, operated, financed and owned by private individuals, who could sell the lighthouse or dispose of it by bequest. The role of the government was limited to the establishment and enforcement of property rights in the lighthouse. The charges were collected at the ports by agents for the lighthouses. (Coase 1974, p. 375)

Reevaluation of the Nature and Efficiency of the Old English Lighthouse System

Coase's empirical material was subsequently reexamined, raising questions about his conclusions. His interpretation of the history of English lighthouses is marked by two forms of bias. First, Coase underestimates the role of public power in the old system of English lighthouses: this system was not strictly private but mixed. Van Zandt (1993, pp. 65–67) stressed that the patents granted by the Crown, or the leases granted by Trinity House, had three characteristics that distinguished them from a private system in which the Government's role is limited to the establishment and enforcement of property rights. The authorization to build and maintain a lighthouse (1) guaranteed a monopoly, (2) set the price of the service, and (3) involved the Crown in the collection of payments. These three aspects are interlinked, since price-setting was becoming necessary to protect users facing a monopoly, while the fixed price (as well as the contract duration and the sharing of the collected dues) determined the monopoly's rent and its distribution.

Second, Coase overestimates the efficiency of the direct relationship between producer and consumer. The service offered by this mixed system was considered expensive and complex, thus motivating the nineteenth century centralization (Taylor 2001). Moreover, the lighting provided by the lighthouses was often poor, and some were not even lit – since the fixed price meant that the only way to increase profits was to lower costs. In addition, the buildings themselves were sometimes erected by individuals who did not avail themselves of all the technical guarantees required. These problems were intensified by a certain form of corruption: patents were granted according to the Sovereign's goodwill, to those he or she favored or to those who offered him or her the greatest amount of money. It was even *because* the Sovereign obtained money when he or she authorized a private individual to build a lighthouse (money he or she would not have obtained if the authorization was granted to Trinity House) that he or she prevented Trinity House

from building lighthouses (until 1679). The high cost of light dues is thus explained by its being a monopoly rent of which the Sovereign collected a share (Bertrand 2006; Carnis 2013).

The nationalization that occurred at the beginning of the nineteenth century was followed by a lowering of dues and an improvement in technology, mainly thanks to the fact that research on optics was now being undertaken by engineers (the Stevenson dynasty) at a national level. They worked in close cooperation with the French government and its engineers (Augustin, then Leonor Fresnel), and with French and English industrials (Soleil, which later became Sautter; and Chance Brothers) (see Elton 2009). In fact the centralization aimed at implementing the most recent innovations in lighting, which had been developed in France but were too expensive to be imported by private English owners (Levitt 2016).

The French Lighthouse System: The Advantages of Centralization

The French lighthouse system, which had been centralized at the end of the *Ancien Régime*, confirms the potential advantages of centralization when compared to the decentralized English system (therefore, in the period 1790–1830) (Bertrand 2005).

The French Revolution gave control of lighthouses and beacons to a service within the Ministry of the Navy, and the Empire then transferred this role to a Lighthouses Service, created in 1805 and falling under the *Direction des Ponts et Chaussées* (within the Ministry of the Interior). The control of this service was eventually granted to the Lighthouse commission, a “place of scientific and political deliberation” created in 1811 and composed of engineers, scientists, and naval officers (Guigueno 2001, p. 99; compared to Trinity House, which was made up of retired ship-owners and honorary members). This commission explicitly thought of all the French coastal lighthouses as a system: its 1825 report planned a network of lighthouses along the French coasts. The French system was the source

from which the great technological innovations (like the Fresnel lens) were diffused. This technical superiority was linked to the administrative structure of the system, centralized and composed of engineers. Centralization opened the way to the testing of new techniques on several lighthouses before an authoritative application on all the coasts, which implied scale economies.

The two systems may therefore be opposed: on the one hand, the French centralized system, supervised by engineers and scientists, financed by general taxation, with building planned along the coasts according to a consistent national scheme; on the other, the pragmatic English system, more decentralized, supervised by honorary members, subject to favoritism, financed by light dues, and with the building of lighthouses determined by dramatic wrecks (Guigueno 2001, pp. 108–109).

While the French system of lighthouses is the archetype of the centralized model, it had not always been centralized. During the *Ancien Régime*, it was closer to the English dues system but with another mix of private and public that proved less efficient. We may take the example of the Cordouan lighthouse, in the Gironde estuary leading to Bordeaux, whose history is the best known (Bertrand and Guigueno 2016). This first French lighthouse was in fact the first *English* lighthouse: a tower was built there by the Black Prince, Edward of Woodstock, between 1360 and 1370. A document from 1409 testifies that dues were raised by a hermit to finance a reconstruction that had already become necessary. England would generalize the dues system for its lighthouses, as we have seen, and France would also retain it, but in a less efficient manner. During the fifteenth and sixteenth centuries dues were raised on ships entering the Gironde to finance a new lighthouse at Cordouan. Finally, after numerous complaints that dues were being raised although the tower was not being built, under the orders of the kings Henri III and then Henri IV, a new tower was designed by the architect Louis de Foix and completed in 1611: it was a Renaissance splendor, financed by dues and specific local taxes (at the municipal and regional levels). The situation rapidly deteriorated: dues were still being raised, but

the tower was already in ruins at the beginning of Louis XIV's reign. Dues were then raised by a receiver in the name of a "governor of the tower of Cordouan" but apparently did not go to the lighthouse. An entrepreneur was commissioned to maintain the tower and the light; he obtained this charge by auction to the lowest bidder. To win it, he proposed too low an amount to cover the expenses linked to the maintenance of the tower and the furniture for lighting. This is why during the seventeenth and eighteenth centuries, the tower was often not lit. The lighthouses system began to be centralized at the end of the *Ancien Régime*: Tourtille-Sangrain then Teulère were sent by the King to improve the structure and the lighting of Cordouan. And dues were de facto abandoned in the last decade of the eighteenth century.

Conclusion

At the turn of the nineteenth century, lighthouses, which were more or less privately provided with the help of the state, were nationalized not only in England and France but also in Estonia (Poder 2010) and Sweden (Lindberg 2015). A change of lighting technology may explain this change. From local lights, made excludable because the harbor was a complementary good to the lighthouse service (Varian 1993), improvements in the technology of lights made coastal lighthouses possible: the lighthouse became nonexcludable, which accounts for its nature as a "public good." Finally, the existence of "private" (local) lighthouses in the old English system, as brought to light by Coase, does not refute the assertions of economists like Mill and Samuelson that (coastal) lighthouses could more efficiently be produced by the state (Levitt 2016).

Limits of Contracts

[Behavioral law and economics of contract law](#)

Definition

Limits of contracts refer to a number of exceptions in contract law to the rule that courts should fully enforce voluntary agreements between capable parties.

Introduction

Economic analysis and the rational actor model have dominated contract scholarship for at least a

generation. More recently, a group of behaviorists has challenged the ability of the rational choice model to account for contracting behavior. Numerous tests done by psychologists and experimental economics have shown that people often do not exhibit the kinds of reasoning ascribed to agents in rational choice models (Tversky and Kahneman 1974). Behavioral economics incorporates evidence of decision-making flaws that people exhibit to model consumer markets in which sophisticated firms interact with boundedly rational consumers. Behavioral law and economics uses existing scholarship in both cognitive psychology and behavioral economics to explain legal phenomena and to argue for legal reforms. For most of the legal scholars who apply behavioral approaches to contracts, evidence of cognitive biases provides at least a *prima facie* case for more paternalistic forms of legal intervention rather than strict reliance on freedom of contract. The premises of neoclassical law and economics push in the direction of freedom of contract: if parties are rational, they will enter contracts only when it is in their self-interest, and they will agree only to terms that make them better off; otherwise, they would not have voluntarily agreed to them (Posner 2003). Behavioral economics rejects the assumption that people are rational maximizers of their satisfactions in favor of assumptions of “bounded rationality,” “bounded willpower,” and “bounded self-interest” (Jolls et al. 1998). Bounded rationality refers to the fact that people have cognitive quirks that prevent them from processing information rationally, such as availability bias, overconfidence and overoptimism bias, the endowment effect, and status quo bias. The cognitive bias literature generally favors expanding the range of government regulation to address a wide variety of business practices that exploit the biases of consumers, or at least some consumers. Sunstein and Thaler (2003) advocate “libertarian paternalism,” an approach that preserves freedom of choice, but encourages both private and public institutions to steer people in directions that will promote their own welfare. The new paternalist claim is that deliberate structuring of decision contexts – such as assigning appropriate default options, providing cooling-off periods for

commitments, targeted disclosure, and so forth – can in principle enhance individuals’ welfare. This contribution represents the behavioral account as well as the neoclassical economic account of a number of contractual practices, clauses, and rules. It includes the penalty clause, pro-consumer default rules, the cooling-off period, automatic renewal provisions, choice manipulation, add-on and multidimensional pricing, and contracts with deferred costs.

Penalty Clauses

One of the earliest applications of behavioral insights to contract law was made by Melvin Eisenberg (1995) who attributed the courts’ reluctance to enforce penalty clauses to the limits of cognition. A penalty clause is a contractual provision that liquidates (fixes) damages in excess of the actual loss from contract breach. According to Eisenberg (1995), a special scrutiny of liquidated damages and penalty clauses is justified because such provisions are systematically more likely to be the product of limits of cognition. Parties at the bargaining stage are generally overoptimistic about their ability to perform and will sacrifice the detailed bargaining necessary to achieve an effective damage provision. The policy implication of this observation, according to Eisenberg, is that it is proper for courts to scrutinize these provisions more closely. Hillman (2000), however, argues that behavioral decision theory cannot resolve the puzzle of liquidated damages. Although some phenomena like overoptimism support the scrutiny of this provision, other cognitive heuristics and biases support strict enforcement of the provision. First, assuming that parties consider the default rule – here the award of expectation damages – as part of the status quo, contracting around the default and agreeing to liquidated damages suggest that the term must be very important for parties and that they bargained over the provision with care. Second, assuming that cognitively limited parties do not like ambiguity, they may prefer the safety of a liquidated damage provision over the uncertainty of expectation damages. Third, judges who exhibit

hindsight bias will overestimate the parties' abilities to calculate at the time of contracting the actual damages that would result from breach. Because judges will believe that the parties' remedial situation at the time of contracting was not ambiguous, judges will undervalue the importance the parties attach to the agreed-upon damage provision. For these behavioral reasons, courts should presume the enforceability of such provisions rather than making every effort to strike them out. Rachlinsky (2000) does not agree with these arguments. The status quo bias does not justify deference because the increased effort to bargain around the damage rule does not necessarily eliminate the effects of overoptimism. And although aversion to ambiguity justifies deference to liquidated damages, courts actually use this insight under the penalty doctrine by giving more deference to liquidated damages when damages are hard to calculate (and thus ambiguous). Eric Posner (2003) states that the behavioral account of the penalty doctrine cannot explain why the biases justify judicial scrutiny of liquidated damages but not other terms. If parties overlook low-probability events, then any contract term that makes obligations conditional on events that occur with a low probability could be defective on a behavioral account, but because they are not liquidated damages, actual courts do not subject them to scrutiny. The behavioral approach does not seem to explain existing contract law. It may also not provide a solid basis for normative recommendations for reforming contract law. Monumental floodgate problems would be created if courts were to police potentially all contract provisions to account for parties' irrationality in processing information. This would undermine contract law's goal of certainty and predictability (Hillman 2000).

The economic explanation for legal intervention rests on the argument that people tend to sign contracts without reading them (Goldberg 1974; Katz 1990). If contract drafters know that some parties will not read the document before signing, they can abuse that fact and incorporate clauses that benefit the drafter at the expense of the signers, with no corresponding welfare gains. Strict enforcement of contracts would imply a

duty to read and understand contracts before signing. It is however costly to read, evaluate, and understand contract terms. There are costs of consulting an expert and costs of time spent in reading and trying to understand the small print. Since rational parties balance the costs and benefits from reading and understanding contracts, it can be rational not to read when the costs are higher than the expected gain that a person stands to reap from reading and understanding contracts. This is likely to be the case for reading and understanding the contract terms' implications for rare events. Research in psychology and behavioral economics which suggests that most people are poor at estimating probabilities correctly can enrich the analysis at this point. To the extent that they systematically underestimate the probability of a rare event, they are unlikely to invest in understanding what the contract stipulates for rare events. The signing-without-reading problem can be sensibly addressed by a legal prohibition of contract terms which rational and informed parties would never accept (De Geest 2002). Rational and informed parties would never accept a contract term of which the costs to the debtor are higher than the benefits to the creditor. The fact that such a term is nevertheless adopted in a contract is implicit evidence that one of the parties did not read or understand the contract (Rea 1984). De Geest and Wuyts (2000) have shown that penalty clauses are in most cases irrational, providing in this way an economic ground not to enforce them.

Pro-consumer Default Rules

Pro-consumer default rules are a consumer protection technique commonly employed in American contract law, but also in European contract law. Sticky default options are a growing trend in consumer protection law (Bar-Gill and Ben-Shahar 2013). Parties can opt out, but the procedure for these opt-outs is more rigorous and costly. For example, the Common European Sales Law (CESL) rules on product conformity set high warranty standards which can be circumvented, but any agreement derogating from the requirements to the detriment of the

consumer “is valid only, if, at the time of the conclusion of the contract, the consumer knew of the specific conditions of the goods or the digital content . . .” (art. 99 (3) CESL). The technique is also used in labor law to protect employees. The behavioral justification for changing default rules – and sometimes making the default costly to change – is that people are subject to framing effects. This means their decisions tend to be sensitive to seemingly irrelevant aspects of how the choice situation is framed. Probably the best known type of framing effect is the endowment effect (Kahneman et al. 1990), which refers to people’s tendency to demand more compensation to give something up (their willingness to accept) than they would have paid to acquire the same thing (their willingness to pay). For rational agents, the default should not make a difference for choices (at least if transaction costs are low). But for less-rational agents, the default rule can matter. Employees, for example, might demand more compensation to eliminate a for cause termination clause than they would sacrifice to insert it. Sunstein and Thaler (2003) therefore suggest making “for cause” rather than “at will” the default employment termination rule. Yet behavioral theory does not provide policymakers with an answer to the question which default rule corresponds to the agent’s true preferences.

According to Verkerke (2015), legislators may choose pro-consumer default rules for another reason: such defaults may be thought to serve the purpose of better informing parties about the legal rules which apply to the transaction. People often lack basic information about the legal rules governing particular transactions in which they are routinely involved. Abundant empirical evidence reveals widespread ignorance about many aspects of civil law. When people do not know important legal characteristics of the things they buy, their willingness to pay may not accurately reflect their true valuation of those products and services. Information-forcing default rules suggest a possible solution to this problem of legal ignorance. Lawmakers could determine whether one party has a comparative advantage in obtaining and communicating information about the law governing the transaction. Then they

could select a default rule that disadvantages the better informed party knowing that the overwhelming majority of well-informed parties will opt out by drafting contract terms that meet certain standards for clarity. If so, a legal-information-forcing rule would force the comparatively better informed party either to reveal the relevant legal information or to accept a default rule that favors the less informed party. In order to escape the unfavorable default, the informed party must disclose information to her less well-informed contractual partner. Such a rule contrasts sharply with a conventional “majoritarian default” selected to mimic the terms that most parties would prefer for this type of transaction. However, if the purpose of these default rules is to convey legal information to all, or even many, unsophisticated parties, that objective is likely to be frustrated, according to Verkerke (2015). One salient fact about legal-information-forcing rules is that the targeted information is most often communicated in a standardized form contract such as a bill of sale, an employee handbook, a standard form insurance contract, a release of liability, or a rental agreement. Almost no one reads contracts carefully enough to digest the legal information that these default rules are designed to force, which may lead to the signing-without-reading problem. A legal requirement according to which opt-out is allowed only after the consumer expresses conscious, informed consent may be seen as procedural evidence (evidence about the circumstances of contracting) that there is no signing-without-reading problem (De Geest 2002). Ayres and Schwartz (2014) observe that consumers need not read to learn about prevailing contract terms. Instead, they form expectation about terms based on what they learn from store visits, read in the media, experience in their own transactions, and hear from friends. These beliefs may accurately correspond to the content of a particular contract. Or consumers may suffer from “term optimism” – a mistaken belief that a contract’s terms are more favorable than the provisions actually included in its text. Ayres and Schwartz (2014) propose an elaborate contracting regime designed to combat term optimism. Their system would induce mass-market sellers to survey consumers periodically to

determine if those consumers correctly understood the terms of the seller's agreement – a process they call “term substantiation.” Sellers then would be required to use a standardized warning box to disclose any terms that consumers mistakenly thought were more favorable. Terms that meet or exceed the median consumer's expectations would not have to be included in the warning box, to prevent overuse of the box. Behavioral support exists for targeted warnings instead of ever-expanding disclosures. People tend to read more when there is less to read (“less is more”) and tend to take more relevant criteria for decision-making into account when there is less choice, a phenomenon called the “choice paradox.”

Cooling-Off Periods

When cooling-off periods apply, contracts are not enforceable in the standard way, namely, from the moment the contract is concluded, but instead can freely be canceled within a certain time period after the conclusion of the contract. During the cooling-off period, consumers have the right to withdraw from the contract at no cost and for no reason, contrary to the general principle that contracts are binding (i.e., *pacta sunt servanda*). European law gives consumers the right to withdraw for a range of contracts for goods and services, such as doorstep selling transactions, time-share contracts, distance selling, and credit contracts (Eidenmüller 2011).

The behavioral support for cooling-off periods is the evidence that people make different decisions depending on whether they are in a “hot” or “cool” state (Loewenstein 2000). According to Sunstein and Thaler (2003), the essential rationale for cooling-off periods is that under the heat of the moment, consumers might make ill-considered or improvident decisions that they would not make if they were in a cool state. Both bounded rationality and bounded self-control are the underlying concerns. The legal provision of a cooling-off period allows the decision-maker to reconsider his decision once he is in a cooler mental state, but structures the decision context in other behaviorally relevant ways. The evaluation now takes place in

a state where the decision-maker already possesses the goods. The endowment effect refers to the tendency of people to value things more when they own them (Thaler 1980). Status quo bias and the pervasive drive for consistency may render the cooling-off period inoperative (Hoeppner 2014). To create an optimal cooling-off policy justified on the basis of hot-state bias, policymakers need to know the extent of any given bias, the rate at which the particular hot state dissipates, and the self-debiasing measures adopted by individuals and have to deal with the problem of interdependent biases and heterogeneity in the population. Rizzo and Whitman (2009) argue that policymakers do not have access to all the knowledge needed to implement welfare-improving paternalistic policies.

There is also a plausible economic basis for the right to withdraw (Rekaiti and Van den Bergh 2000; Ben-Shahar and Posner 2011). The economic rationale for the right to withdraw is based on the fact that ex ante information costs (before the contract is concluded) may be higher than the information costs ex post when the consumer is able to inspect the goods he has in his possession. Faced with high ex ante information costs and immediate binding force of the contract, a consumer may rationally decide not to buy a good. This effect is unfortunate from the standpoint of both consumers and firms. Some welfare-enhancing transactions do not take place due to high transaction costs. The right to withdraw then exists to minimize information costs and will increase the number of transactions compared to the status quo ante. Buyers are more likely to buy a good if they have the right to return it if they do not like it. According to the neoclassical economic approach, a case can be made for making the right to withdraw the default rule for modern market transactions characterized by high ex ante information costs. There is however no need for legally mandated withdrawal rights since market parties have incentives to offer them voluntarily. As a matter of fact, many stores have return policies even when they are not legally required to have them. A legal mandate would remove the signaling-of-quality function that return policies may have.

Automatic Renewal Clauses

An automatic renewal clause is a contractual provision according to which a contract is automatically renewed for a new term unless it is canceled. From a behavioral perspective, an auto-renewal clause is considered to be a provision for automatic (default) enrollment in subscriptions and contracts whereby consumers are allowed to opt out, as opposed to the practice of manual renewal which is a practice of not enrolling consumers until they opt in. The behavioral case for default enrollment is based on inertia or status quo bias: the psychological tendency of people to maintain current arrangements, whatever they might be (Samuelson and Zeckhauser 1988). For example, adherence to pension savings plans has been found to increase dramatically when employees are enrolled automatically (Madrian and Shea 2001). That automatic enrollment leads to more enrollment is something which firms know when they adopt automatic renewal provisions in their contracts. Should the use of automatic renewal provisions in contracts be restricted on the ground that they may exploit behavioral biases? Not necessarily, because it may also be regarded as a genuine paternalistic measure to help overcome behavioral biases. Suppose that consumers often fail due to status quo bias to enroll under the manual renewal opt-in system, but they would choose to enroll if they simply took the time to think carefully; then, by offering an automatic renewal service, firms are acting paternalistically. However, strict enforcement of an automatic renewal provision implies the danger of renewal without notice. Consumers are not always aware of the fact that and when the contract will renew automatically. Therefore, they may fail to opt out when renewal is not in their best interest which results in allocative inefficiency. Firms may speculate on this fact when they include an automatic renewal clause in the contract. Legislators have addressed this danger of renewal without notice by requiring conspicuous disclosure of automatic renewal clauses and by requiring notice of renewal to be provided by firms a number of days in advance.

Choice Manipulation

An important finding of behavioral research is that values and preferences are not fixed, but depend on endowment, context, or the way in which a choice is presented – a phenomenon designated as “framing.” The choices of a behavioral consumer can be manipulated. For example, due to anchoring bias, a particular choice might become much more attractive when placed next to a very unattractive one. It is well documented that many firms now hire consultants who advise them on how to better exploit behavioral biases of consumers. Such consultants may recommend, for instance, to use decoy pricing techniques. A decoy is a highly priced product that is not expected to be sold, but that only serves to make less-highly priced products look reasonable. Car dealers learn similar techniques to manipulate potential buyers. One such technique consists of asking a series of (irrelevant) questions to which customers are likely to answer “yes.” Then customers are asked whether they would like to buy options for their new car. Apparently, more customers answer affirmatively when this technique is used. Consumers also are more likely to make a choice on buying extra car options when they were asked before to make a choice on an irrelevant matter. Apparently, once the brain is set into a choice modus, it is likely to continue to follow a pattern of choice while neglecting the possibility of not choosing (e.g., to not buy any extra options). These methods to mislead consumers would lose their effect if firms would have to reveal the fact that they try to exploit behavioral biases. According to De Geest (2014), modern law on information duties is best explained by the least-cost-information-gatherer principle. According to this principle, sellers should reveal information on all aspects of which they are the least-cost information gatherer, provided that the information is material. Information is material when the cost to produce and disclose the information is lower than its value to the buyer. Information is valuable when it can influence the recipient’s decision to contract. Does this principle imply a duty to reveal the fact that one uses manipulative techniques? Clearly, the salesperson is the least-cost

information gatherer about her own use of manipulative techniques. But is this information material? Not in an ideal search process, where buyers can instantly see all products on the market, their features, their objectively tested quality, and their final prices. But in practice, search is often sequential or advice based. When search is sequential or advice based, much more information is material than price and quality, including information on the fact that manipulative techniques are used. De Geest (2014) concludes that sellers who use manipulative techniques should honestly reveal the fact that they use them. In the absence of such a duty, markets would be governed by the caveat emptor principle (“buyer beware”), which leads to allocative inefficiency, distributive distortions, wasteful precaution, and transaction avoidance.

Add-On and Multidimensional Pricing

In a wide range of plausible situations, firms systematically give the impression that the price is lower than it will in fact turn out to be. A common reason for this is that part of the service which many consumers will want is not included in the “headline” price used in marketing (Armstrong 2008). In many businesses, it is customary to advertise a base price for a product and to try to sell additional “add-ons” at high prices at the point of sale, such as extended warranties, shipping fees, and hotel phone and minibar charges in the hotel room. Add-on prices are not advertised, and they would be costly or difficult to learn before one arrives at the point of sale. For example, online, some auctioneers have tried to bury shipping costs deep in an item’s description so that casual bidders will overlook the fee. A fraction of consumers (the “sophisticates”) either observe or foresee the high price of the add-on product and can substitute away from it at little cost. They could decide in advance whether or not to buy the extended warranty, rather than have to make this decision under pressure from the sales assistant. Naive consumers do not consider that they may want the add-on product until they have purchased the main item. They fail to take

add-ons into account when comparing product prices across firms. Gabaix and Laibson (2006) show that competition will not induce firms to educate the public about the add-on market, even when unshrouding is free. The reason for this is a phenomenon which they call the “curse of debiasing.” Educating a consumer about competitors’ add-on schemes effectively teaches that consumer how to profitably exploit those schemes, thereby making it impossible for the educating firm to profitably attract the newly educated consumers. From a policy perspective, they argue that regulators might compel disclosure or could warn consumers to pay attention to shrouded costs. The duty to disclose information in a conspicuous way (instead of shrouding information) can be supported on economic grounds. The practice of shrouding information is a violation of the principle that the least-cost information gatherer should disclose information in the most efficient way. The practice of hiding information and untimely disclosure artificially increases search costs for all consumers, not only the unsophisticated ones.

Oren-Bar-Gill (2004, 2006, 2008) points out that consumers face difficulties in assessing information about the true product price and quality in case of multidimensional pricing and bundling. Examples are rebates, credit card pricing, bundling of printers with ink, and intertemporal bundling in subscription markets like health clubs. In these cases, consumers need additional information about use patterns in order to assess the price and quality (value) of the contracts correctly. For example, in order to assess how expensive the combined purchase of printer and ink really is, the consumer needs to know the price of the printer and the price of an ink cartridge, but also how often he will need to replace the ink cartridge, which depends in turn on the frequency of his use. In order to assess the price and value of health club subscription, consumers need to know the subscription price and the quality of the club services, but also how often they will attend the health club. Consumers who misperceive their future use will make use-pattern mistakes. For example, consumers may overestimate their likelihood of redeeming their rebate, underestimate

the likelihood of paying their credit card bills late, underestimate the amount of printing, or overestimate the number of times that they will visit the health club. To the extent that these mistakes are systematic, they may be due to cognitive biases, like the overconfidence and overoptimism bias. Bar-Gill argues that the importance of use-pattern mistakes requires more and better use-pattern disclosure. In particular, sellers should be required to provide average or individualized use-pattern information. For example, the disclosure apparatus of credit cards should include the amount that an average consumer pays in late fees and how much the individual has paid in late fees over the last year.

Contracts with Deferred Costs

Bar-Gill (2012) shows how a firm that faces a market of myopic consumers can exploit this flaw. Firms can do this by stacking benefits of a contract at the beginning of the contract term and leaving the costs for later. Deferred costs exploit the intense preference that some consumer may have for immediate gratification. This myopia leads them to underestimate whether and how often they will fall prey to the deferred fees that many consumer contracts impose. When consumers evaluate agreements with up-front benefits and deferred costs, they may be tempted by the benefits – such as low introductory interest rates or a subsidized cell phone – while also believing that they will not have to pay the later costs. Bar-Gill adheres to disclosure as the most desirable means to remedy consumer myopia. Badawi (2014) is skeptical that disclosure will be an effective guard against myopia. More extreme measures may be necessary to prevent the harm that the weakness of the will might cause, just like Ulysses has asked his men to strap him to the ship's mast to prevent him from succumbing to the sirens. Bar-Gill points out that firms have little incentive to provide myopia-limiting products. Should legislators take paternalistic measures upon request? Any legal restriction on contract terms needs to be done cautiously, according to Badawi (2014). There are potentially

welfare-enhancing reasons why firms might want to offer low introductory rates that increase substantially after a set period of time. A prohibition of the ability of firms to tantalize consumers with low introductory offers may harm the welfare of the rational, nonmyopic consumers. A behaviorist might see these marketing techniques as temptations to overconsume, while a pure rationalist might see them as attempts to induce an informed switch. How do we know what to do when theory can justify both intervention and the free-market status quo? According to Badawi, the lack of a clear answer to this question suggests that there is a pressing need for data that can discern whether rationality or myopia prevails. In the absence of such data, the decision to regulate or not will largely be a function of the strength of prior beliefs. In societies with a strong belief in the benefits of free markets, there will be more freedom of contract, but also more behavioral manipulation of consumers camouflaged as offering free choice (De Geest 2013).

Liquidation Preference

► Absolute Priority

Litigation and Legal Expenses Insurance

Myriam Doriat-Duban

Department of Economics, BETA UMR 7522,
Université de Lorraine, Nancy, France

Abstract

Legal expenses insurance (LEI) covers all or a part of financial expenses occurring during a lawsuit, in exchange for the payment of a premium by the policyholder to the insurer. It makes access to justice less expensive by shifting the litigation costs from the litigant to the insurer. LEI covers many types of conflicts (labor litigations, consumer disputes, personal injuries, or medical malpractices), but some are generally excluded (divorces). LEI could have some significant effects on conflict resolution, not only for the litigants themselves but also for society. Thus, in the law and economics literature, three topics are generally studied: the consequences of LEI on conflict resolution and social welfare, the influence of the insurer in the litigation, and finally the access to justice by a comparative approach between LEI and legal aid and contingent fees.

Synonyms

Legal cost insurance; Legal insurance; Legal protection insurance

Definition

Legal expenses insurance (LEI) covers all or a part of financial expenses occurring during a lawsuit, in exchange for the payment of a premium by the policyholder to the insurer. There exist two types of LEI: on the one hand, before-the-event (BTE) which covers litigation costs that could be incurred in a future case, and on the other hand, after-the-event (ATE) which covers future legal expenses in a case that has already occurred (the economic literature only deals with BTE LEI, which is the most usual one). Insurers can propose a specific LEI policy or add this insurance to another one, for example, household insurance. This type of insurance covers many types of conflicts such as labor litigations, consumer disputes, personal injuries or medical malpractices, but some are generally excluded, such as divorces. In this respect, it does not constitute a perfect substitute for alternative financing for lawsuits (legal aid or contingent fees).

Introduction

Access to justice is costly for litigants (lawyers' fees, procedural costs, costs of appraisals, etc.). Some systems exist to make access to justice less expensive, among them legal expenses insurance that shifts the litigation costs from the litigant to an insurer. This system prevails in Europe whereas contingent fees, which are forbidden in most European countries, are the main alternative in the United States. Interest in LEI has risen with the increasing weight of legal aid in the budget of European States. Policymakers in many European countries (United Kingdom, France, Belgium, etc.) have tried to develop demand for LEI, which remains underdeveloped for several more or less relevant reasons: alternatives for access to justice (especially if legal aid is "relatively generous"), adverse selection if the insurer cannot identify the real risk of the policyholder, moral hazard if the insurance spurs the insured party to adopt a riskier behavior or to go to trial more frequently, positives externalities in terms of deterrence, and free rider problems for potential victims who have less

incentive to be insured (Faure and De Mot 2012). Policies in favor of LEI attract the interest of law and economics scholars because LEI could have some significant effects on conflict resolution, not only for the litigants themselves but also for society. The law and economics literature can be divided into three parts: (1) authors who have developed economic models to study only the consequences of LEI on conflict resolution and social welfare, (2) authors who have studied the influence of the insurer in the litigation, and (3) authors who have adopted a comparative approach between LEI and alternative financing for access to justice, mainly legal aid and contingent fees.

Impact of LEI on Conflict Resolution and Social Welfare

Most authors study the consequences of legal expenses insurance on conflict resolution. Among them, Kirstein (2000) demonstrates that for the plaintiff LEI has a positive effect on his/her strategic position by making his/her threat to sue more credible, especially in cases with a negative expected value. More precisely, by decreasing the policyholder's legal costs, some cases with negative expected value might become positive and this makes the plaintiff's threat to sue credible. For cases with positive expected value, the negotiation gap widens (the plaintiff requests a higher amount while the defendant offers a lower amount because LEI covers their legal costs) and the amount of the agreement increases (the plaintiff's threat to sue becomes more credible).

Heyes et al. (2004) extend Kirstein's paper by studying the insurance decision of a risk-adverse plaintiff and the effects of this insurance on settlement amounts, settlement probabilities, volume of accidents and trials. They show that the plaintiff chooses to be insured if and only if he/she plans to refuse the defendant's offer. Conversely, he/she chooses to be uninsured if he/she plans to accept the agreement. The effects of LEI on the plaintiff's bargaining position explain this result. Indeed, LEI reduces his/her legal costs and thus increases his/her incentive to go to trial and to reject the defendant's offer. This higher bargaining power

can have a negative impact on settlement so that the probability of settlement decreases and the number of trials rises. Thus, LEI appears to encourage access to justice instead of alternative dispute resolution. But LEI could have a positive effect if these higher incentives to go to court increase the defendant's level of care. Finally, the overall effect is unknown and depends on the plaintiff's risk aversion. Consequently, LEI can increase or decrease social welfare.

Van Velthoven and van Wijck (2001) confirm that the effect of LEI on social welfare is uncertain because the deterrence is improved but at the same time, the number of trials increases. For liability cases, they explain that LEI makes the strategic position of the plaintiff stronger. The effect of LEI comes into play not only *ex post*, during the conflict, but also *ex ante*, where potential injurers will take greater care if they anticipate that plaintiffs are insured against litigation costs. Thus, LEI could have a preventive role and hence a positive impact on social welfare, but only if the expected prevention gains offset the losses of welfare due to the higher number of trials.

The Influence of the Insurer in the Litigation

Visscher and Schepens (2010) analyze the multi-party relationship in a conflict where the litigant has taken out a LEI policy. They explain that the specificity of this insurance lies in the joint presence of several actors: plaintiff, defendant, insurer, and lawyers. Interactions between these actors create conflicts of interest due to agency relationships where, for example, the plaintiff delegates the defense of his/her interests to a lawyer or an insurer. There could also be a specific relationship between the lawyer and the insurer, in particular if the insurer employs the lawyer (especially in the stage of bargaining in the shadow of the law). Visscher and Schepens (2010), like Kirstein (2000) and Heyes et al. (2004), confirm that LEI increases the credibility of the threat of trials by reducing the plaintiff's legal costs. The worst situation in terms of arrangement is where both litigants are insured:

freed from their trial costs, both have more incentive to go before the judge. Nevertheless, the interests of the insurer have to be taken into account. The insurer's aim is to minimize the legal costs it covers. This is what is at stake in the agency relationship between the litigant and his/her insurer: the insurer may incite its uninformed client (on his/her rights or the actual compensation to which he/she is entitled) to accept an agreement, not always in his/her best interests but just to save legal costs. Visscher and Schepens add that the impact of this type of "disadvantageous" agreement for the insured on the reputation of the insurer may not constitute a safeguard against these practices.

Finally, Qiao (2013) takes into account the role of the insurer in the negotiations, studies the three-way relationship between the client, the lawyer, and the insurer, and determines the optimal LEI. He shows in particular that demand-side cost-sharing is necessary to design an optimal LEI. More precisely, the plaintiff is required to share the cost of the service received to mitigate his/her incentive to overuse the insurance.

Comparative Analysis Between LEI and Two Alternatives: Contingent Fees (CF) and Third-Party Litigation Funding (TBF)

Some other authors adopt a comparative and more normative approach. Their aim is to compare several systems whose aim is to allow access to justice and to determine which of them maximize social welfare.

In this perspective, to choose between two alternative systems, Baik and Kim (2007) compare the American practice of contingent fees with the European practice of legal expenses insurance. They introduce the role of the lawyer through the type of fees. They study the American system by considering that the plaintiff's lawyer works on a contingent-fee basis and the defendant's lawyer on an hourly fee basis. For the European practice with legal expenses insurance, the defendant may have to purchase a LEI policy and both lawyers work on an hourly fee basis. They show that the

plaintiff's expected payments are higher under a legal insurance system than under a contingent fee system but litigants' legal expenditures are also higher because the lawyers are likely to be more aggressive.

Friehe (2010) compares contingent fees and LEI, two systems which help liquidity-constrained litigants to finance their case. He generalizes the previous results by introducing the defendant's degree of fault. He finds that the performance of both regimes (in terms of expected plaintiff payoffs, plaintiff and defendant expenditures, total contest effort, incentives for delegation, and justice) is highly dependent on the defendant's fault.

Ancelet et al. (2012) extend the analysis of Heyes et al. (2004) by studying the consequences of a substitution between LEI and legal aid on conflict resolution. Their results differ significantly from those of Heyes et al. (2004) who study only LEI and show that LEI is taken out only by plaintiffs who anticipate going before the judge, regardless of their risk-aversion. The introduction of the choice between legal aid and LEI modifies the analysis. Indeed, the plaintiff can take out LEI even if he/she anticipates an arrangement or, conversely, prefers legal aid if he/she expects to go to trial. But they show also that the agreements accepted by plaintiffs if they are covered by LEI are superior to those required if they are beneficiaries of legal aid, regardless of their risk-aversion. Accordingly, under the authors' assumptions, legal aid seems more favorable to agreements than LEI, because it makes the plaintiffs less demanding (they accept a lower offer under legal aid than under LEI). The development of LEI could then appear desirable for litigants (who would obtain better arrangements) but not for the legislator if its aim is to reduce access to courts.

Moreover, in the same way that insurers want to encourage an out-of-court settlement in order to reduce their own costs, the lawyer who is poorly paid in a legal aid system may encourage agreement instead of judgment to avoid additive costs. Thus both legal aid and LEI may encourage their clients to settle the dispute even if it may be worthwhile for these clients to go to court.

Everything is then played out within the agency relationship between the lawyer and the beneficiary in the case of legal aid, and the insured and the insurer in the case of LEI.

In an empirical study in the Netherlands, van Velthoven and Klein Haarhuis (2011) examine the relationship between the decision to use the justice system, whether or not with LEI, and the income of individuals (divided into three classes: those who can benefit only from legal aid, those who are eligible for legal aid but can also take out LEI, those who can only take out LEI). They show that, all other things being equal, the likelihood of using a judge is 11% higher for litigants insured through LEI than for the others. There are two reasons for this. First, there appears to be a selection effect in that individuals who have already had a case brought before the courts are more inclined to take out LEI. Secondly, there is a moral hazard problem since insured individuals are more likely to go before the judge, because LEI covers their costs of litigation.

Finally, Faure and De Mot (2012) compare LEI and Third-Party Financing Litigation (TPLF) with the idea that LEI could be a barrier to the development of TPFL. The answer is negative, mainly because LEI is underused in the United States and many European countries. Their analysis shows that TPFL is not necessarily worse than LEI in terms of volume of litigation, quality of litigation, or timing of settlements. Moreover, in Europe there is hostility towards TPFL, because the trial is considered as a risk rather than a way to enforce the law.

Conclusion

The impact of LEI on litigation is complex because several effects interact. Some authors examine its impact on litigation in a positive light. Others adopt a more normative approach and compare the effects on litigation of LEI relative to the effects of other avenues of conflict financing (legal aid, contingent fees, TPLF). Empirical studies are still too scarce to highlight the theoretical results. Moreover, LEI ought to be more developed in Europe where it is still underused.

Litigation and Marital Property Rights

Antony W. Dnes
Northcentral University, Arizona, AZ, USA

Abstract

The article examines the function of marriage and associated incentive properties in relation to ancillary relief (often referred to as “settling up”) following divorce. Many countries have

experienced growing divorce rates, a decline in marriage, increased unmarried intimate cohabitation, and the delaying of marriage and childbirth to a later age. There has also been a recent increase in the pressure to extend marriage formalities to same-sex couples. All of these changes raise questions concerning the incentive structures attached to marriage and divorce. Major incentive issues arise whenever there is public-policy debate about changing the law of marriage and divorce with associated implications for litigation. It is vital to understand the economics underlying the debate since there is a danger that well-meant reform might lead to adverse unintended consequences.

Introduction

Over the past 50 years, many countries have experienced growing divorce rates, a decline in marriage, increased unmarried intimate cohabitation, and the delaying of marriage and childbirth to a later age. That commentary would once have been restricted to western societies, but the trends have begun to appear in developing economies: for example, the Chinese divorce rate increased by almost 13% in 2013 (*South China Morning Post*, March 11, 2015, “Heartbreaking news: China’s divorce rate jumps 13pc as more choose to untie the knot.”). In the USA, the divorce rate per thousand population has fallen in recent years, although as a result of marriage rates falling; the divorce rate per thousand marriages continues to rise (See data collected by the US Center for Disease Control at http://www.cdc.gov/nchs/nvss/marriage_divorce_tables.htm). These trends have caused concern, not least because of the unsettling nature of the apparent social instability. Additionally, and one might say curiously since heterosexuals are avoiding marriage, there has been a recent increase in the pressure to extend marriage formalities to same-sex couples. All of these changes raise questions concerning the incentive structures attached to marriage. Major incentive issues arise whenever there is public-policy debate about changing the law of marriage

and divorce with associated implications for litigation. It is vital to understand the economics underlying the debate because there is a danger that well-meant reform might lead to adverse unintended consequences.

Underlying the incentive structures in intimate partnerships, we find a potential for exploitation by at least one of the partners: a hold-up problem. This can arise if long-term promises induce detrimental reliance, such as one partner's giving up work to become a homemaker, in expectation of long-term benefits such as shared ownership of property and nonpecuniary benefits such as marital consortium. Under weak enforcement of promises, one partner could opportunistically make promises and then subsequently renege on them. The economic analysis of marriage and divorce has tended to focus on problems associated with the post-WWII easing of divorce law. Failure to enforce promises or compensate for breach by the promisor can create an adverse incentive structure identified as a "greener-grass" effect (Dnes 1998, 2011; Dnes and Rowthorn 2002). The effect is often associated with relatively wealthy men abandoning older wives. However, there is a comparable incentive for a dependent spouse to divorce if settlement payments, based on dependency, allow the serial collection of marital benefits without regard to the costs imposed on the other party: encouraging a "Black-Widow" effect (Dnes 1998). Two related issues concern contemporary unmarried cohabitation: (i) whether a lack of legal support for long-term relationship-specific "investments" results in low-quality commitment where more commitment could be beneficial and (ii) whether assimilating same-sex unions into marriage or marriage-like structures creates high-quality commitment signals, or whether these signals are irrelevant in such relationships (Dnes 2007).

Marriage and Opportunism

Becker's (1973, 1991) seminal work on the family is based on specialization and the division of labor within the household (Grossbard 2010) and does not really give a clear reason for the emergence of

a state-sanctioned standardized marriage contract. One could just as well cohabit with a grandparent and achieve economies of specialism. The theory is based on a neoclassical approach to rational decision-making (Dnes 2009). It is possible that the hostility toward Becker's work exhibited by some sociological writers might be reduced by moving to a context-dependent, ecological view of rationality (Smith 2008), in which individuals use heuristics to economize on decision-making capacity. Becker's work has led to more recent bargaining theories of the family, which, however, could still relate to cohabitation as much as marriage (Friedberg and Stern 2014).

Cohen (1987, 2002, 2011) pioneered a contractual view of marriage that is firmly anchored in institutional economics and does give a distinctive reason for marriage rather than mere cohabitation: the suppression of opportunistic behavior connected to asymmetries in the life cycles of men and women. Divorce can then be seen as analogous to breach of contract, although it should be noted that marriage predated the development of modern contract law and that fault-based divorce is not exactly the same as breach of contract. For example, no-fault divorce is consistent with legally sanctioning one spouse's desertion, a breach. Furthermore, fault encompasses criminal and tortuous behavior such as assault that is subject to separate legal penalties (Ellman and Lohr 1997) likely to add to deterrence of the behavior. A purely contractual starting point for ancillary relief in divorce litigation would be very modern, although contractual elements can be found in the case law (Cohen 1987, p. 270). A contractual approach is also capable of considerable sophistication, particularly where inherently economic issues like asset division are at stake, or when examining signaling aspects of marriage (Dnes and Rowthorn 2002; Probert and Miles 2009). Finally in this regard, one could base the enforcement of marital obligations on quasi contract, i.e., recognizing the absence of a formal contract and using *equity* rather than *law* as the approach, and still reach much the same results.

Cohen (1987) notes that spouses exchange unusual promises of support where the value of

the support is affected by the attitude accompanying it. In a traditional marriage, domestic services provided by the wife frequently occur early on in the marriage, permitting the husband to concentrate on employment. The wife typically makes nonrecoverable, i.e., sunk, investments in child-rearing and homebuilding early on in the marriage. The traditional male's support will typically grow in value over the longer term. If the opportunities of the parties change, one of them may develop an incentive to breach the "contract." Divorce usually imposes costs on both parties, but costs are asymmetrically distributed in dissolving traditional marriages: the husband typically finds it easier to remarry or repartner (Cohen 1987; Kreider and Rose 2006), whereas the wife has incurred many sunk costs at an earlier stage.

There are both pecuniary and nonpecuniary benefits to marriage. A spouse's willingness to commit is satisfying evidence of love. Marriage also gives a means of protecting long-term investments in marital property. Spouses may be regarded as unique capital inputs in the production of a new output, namely, "the family." In particular, children are important marital outputs. A further instrumental gain is insurance: parties mutually support each other through the ups and downs of life forsaking the freedom to seek new partners, which is rational if the net gains from marriage are sufficiently high (Posner 1992). However, the gains from marriage are surpluses that arise after sunk investments have been made, which can tempt the less-tied-down spouse into opportunistic behavior, specifically into attempts to appropriate the product of the sunk investments. One spouse's incentives to appropriate the gains from marriage may well operate similarly to the incentives arising within joint business ventures (Klein et al. 1978).

Marriage-specific benefits such as the prospect of losing association with children are "hostages" (Raub 2009) that may suppress opportunistic exit from the marriage in some cases. However, judicial approaches to obligations like long-term support can easily lead to too much or too little divorce. This observation brings in the idea of an optimal level of divorce, which might be encapsulated in a rule like "let them divorce when the

breaching party (the one who wants to leave, or who has committed a "marital offence") can compensate the victim of breach," but not otherwise. The underlying welfare perspective in the last sentence is the Kaldor-Hicks *utilitarian* approach of allowing a change when it will increase joint (i.e., social) welfare.

Marriage promises revolve around direct and instrumental benefits, bargaining influences (Lundberg and Pollak 1996), joint goods, marriage-specific investments, and incentives for opportunistic restructuring. Divorce law needs to suppress opportunism, or it may end up creating incentives for litigation and destabilizing marriage. Perceived instability in the marriage contract may then deter some from marrying: fewer marriages will occur than otherwise, and there may be less investment in activities such as child raising (Stevenson 2007).

The preservation of a very clear signal of commitment is particularly important in marriage, which may already be destabilized by inappropriate laws (Rowthorn 2002). Well-meaning legal reforms have tended to decouple obligations from fault in divorce cases, and in doing so have overlooked the importance of enforcing promises that support "investments" in the family. Rationally, it will be the economically weaker spouse who would alter behavior in the face of lower promissory enforcement, for example, increasing the time spent searching for a reliable spouse. Such a search-time effect has been observed empirically (Mechoulam 2006; Matouschek and Rasul 2008): introducing no-fault divorce settlements (as opposed to no-fault divorce rules per se) into US jurisdictions is statistically linked to increases in the age of first marriage. Some US states have responded to the perceived weakening of marital commitment with a "covenant marriage" movement, providing an option for alternative marriage rules making the exit rules tougher.

Divorce Litigation and Liability Rules

It is well known that breach of contract can be optimal, providing that the breaching party pays

compensation for the victim's lost expectation (Posner 2014; Parisi et al 2011). How far does this analogy carry over in a contractual view of marriage? Expectation damage, as the standard common-law remedy for breach of commercial contracts, has the characteristic of requiring the breaching party to pay compensation that places the victim of breach in the position they would have attained had the contract been completed (see Dnes 2005, p. 97). This requirement meets the Kaldor-Hicks welfare criterion since the gainer must gain more than the loser loses to be willing to make the change; the loser is as well off as before. The usual approach to a commercial contract breach also requires the victim to mitigate losses and does not compensate for avoidable losses. For the victim of marital breach, modeling ancillary relief on expectation damages would imply awarding the value of lost pecuniary support and lost nonpecuniary elements of promise such as consortium while making an allowance for the value of alternative occupations that may open up as a result of dissolution. The nonpecuniary elements do not present the inherent difficulties that might be anticipated since courts already make such calculations, for example, in tort cases involving the loss of a spouse.

Basing ancillary relief on court-imposed compensatory damages for lost expectancy applies just one kind of liability rule, in the terms used by Calabresi and Melamed (1972), and it is instructive to consider alternatives. In particular, the same welfare effects, in terms of deterring inefficient breach, could follow from awarding restitution damages aimed at disgorging the breaching party's gains back to the victim of breach. For simplicity, consider a case where the gains exceed the victim's lost expectation. Logically, the breaching party would still make the move if left with just enough of the gains to be slightly better off from divorce. The victim of breach could therefore be overcompensated, but, ignoring for the moment possible strategic considerations affecting the victim, the incentive to divorce for the breaching party would be just the same as under the expectancy liability rule. Therefore, a liability rule requiring compensation of at least the victim's lost expectancy and no more

than the breaching party's gains can support efficient breach.

Awarding anything less than expectancy damages risks making divorce too "cheap" for the breaching party, and, indeed, depriving the victim of the value of promises. Undercompensation is likely to result from approaches based on compensating detrimental "reliance," which would follow from limiting ancillary relief to compensating for lost opportunities such as career options forgone through entering the marriage. The expectancy must have exceeded the reliance, or the spouse would have remained single. Similarly, restitution of "contributions" or combinations of contributions and reliance would tend to undercompensate.

Another approach to settling up after divorce could be based on specific performance, which is generally not favored in relation to commercial contracts mainly because of difficulties of supervision. However, Parkman (1992, 2002) has suggested basing divorce law on a specific-performance requirement for spouses to remain married unless they mutually agree to divorce, whenever they could bargain at low cost. The spouse wishing to leave would have to offer the other at least expectation damages to obtain consent. This approach follows a property rule in the terminology of Calabresi and Melamed (1972) and (Ayres 2005). Parkman claims that an advantage of the specific performance requirement is the avoidance of coercive divorce, although coercion would in fact also be avoided by a (superefficient) court able to carry out precise liability rule calculations. The bargaining might extract the equivalent of restitution damages ("how much can you part with to leave?") rather than expectancy, but would still lead to an efficient result (gainer still gains something after compensating loser). The economics literature on bargaining in the presence of incentives to appropriate gains from trade opportunistically does support the need for the vulnerable party to have complete bargaining power (Rosenkranz and Schmitz 2007).

Bargaining may be impeded by indivisible elements such as the value to parents of contact with children, described by Zelder (1993, 2009) as a marital public good. During marriage, both

parents can enjoy the company of their children, and one parent's enjoyment does not in general reduce the value of the other parent's contact. From a welfare perspective, we should add up both parents' enjoyment (heuristically assuming directly measurable welfare) in valuing the marital public good. Once they divorce, the value of parental contact with the children becomes separable and contact times change. It is possible that the intact marriage has a positive value because of the public good, but a parent without court-awarded child custody may not be able to transfer assets to the other to prevent the divorce. There may be few other assets in the marriage, and the parent with custody retains private enjoyment of the marital public good. This reflection leads to the Zelder paradox: the more the family invested in children, products of love rather than market-valued labor, the more likely is inefficient dissolution. Indivisibilities are also problematic in the more general analysis of suppressing opportunistic bargaining (Rosenkranz and Schmitz 2007).

Consideration of the autonomous welfare of children is not commonly undertaken in the literature on divorce, notwithstanding the UN Convention on the Rights of the Child and national legislation such as the UK's Children Acts. An exception is Bowles and Garoupa (2003), which treats the welfare effects of the divorce on the children of divorcing parents as an externality. As might be expected, a marriage that is no longer efficient from the point of view of the parents' joint welfare may still generate net social benefits if there is enough harm to the children from divorce. That comparison does however beg a nontechnical question that should actually be addressed more frequently in economics: whose preferences are to count? If, as in the common-law world traditionally, minor children are not recognized as possessing mature mental capacity, then the externality cannot be said to arise.

In family law, children's preferences have not typically been *generally* recognized (Cretney 2005; Ellman and Ellman 2008; Ellman et al 2014). It is easy to be misled by the UN Convention, adopted by all countries except the USA and Somalia, which appears to require courts to give primary consideration to children's

welfare, but does this in a restricted sense falling far short of conferring autonomous enforceable rights. Similarly, the UK's Children Act 1989, which is good exemplar of national legislation, requires paramount consideration to be given to the welfare of children in matters relating to their *upbringing*. As Reece (1996) and Potter (2008) both point out, the primacy or paramountcy is required over a very narrow area and is to be sought by a court acting in the interests of the child, a somewhat indirect "voice." The UK Children and Families Act 2014 removed a residual power retained in the Matrimonial Causes Act 1973 under which the court could previously refuse a divorce decree if the court felt the harm to the family's children to be intolerably high. Family law tends not to regard children as fully autonomous "minds" and continues to acknowledge their general lack of capacity. Legal recognition of greater children's rights in divorce proceedings would require a showing, not only that there is an effect on children but also that we should recognize their capacity more.

Types of Intimate Cohabitation

Traditional Marriage

A traditionalist view of the marriage contract sees an exchange of lifetime support for the wife, in which she shares the standard of living of the *marriage*, for typically feminine domestic services such as housekeeping and child-rearing. Could the contract view easily include less traditional frameworks, such as modern marriages where the parties are more economically equal? The marriage contract appears to be a good example of a contract where performance of the parties is interdependent, and where consideration for performance remains executory (Parisi et al. 2011).

Consider first a lengthy traditional marriage that ends in divorce. The parties met early in life, and after some years the wife gave up work to have children and care for them. When she returned to work it was at a lower wage than previously. Then, after 20 years of marriage, the husband petitions for divorce on the grounds of

separation. Their assets have always been held jointly. On a contract approach to breach, the husband would be expected to share property and income to maintain the standard of living his ex-wife would have enjoyed for the *remainder* of the marriage (subject to any mitigation of loss that may be possible).

Expectation damages are identical to the minimum needed to buy the right to divorce under a system where divorce is only available by consent. The court would assess what that standard of living was and determine who had breached the contract by focusing on proximate causes. The fact that the divorced wife gave up work for a while, or now earns less than might have been the case without child-care responsibilities, is immaterial in finding expectation damages. Her own income would contribute to that expectation, as would her own share of the house and other assets and the combined decision-making of the spouses. The divorcing husband would be expected to contribute from his income and his share of the assets to provide that support for his ex-wife, regardless of the impact on his own lifestyle. Any requirement to maintain the standard of living of the children of the marriage could be dealt with separately by the court.

Under a contract approach, the courts would recreate the expected living standard of the wife by adjusting the property rights and income distribution of the parties at divorce. Fault would matter because the court would need to establish who the breaching party was, but this would not rule out calling some dissolutions “no-fault divorce,” which is simply a compensable breach. Fault would be irrelevant in a system of mutual consent, where both parties negotiate a settlement stating that neither was at fault; where bargaining would safeguard expectations. The classical-contracting approach preserves incentives for the formation of traditional families, if that were considered important.

Classical contracting is also consistent with the simultaneous existence of separate legal obligations for the maintenance of children. However, it would only be consistent with a literal interpretation of the clean-break principle favored in much recent family law if sufficient property rights can

be transferred to avoid the need for subsequent periodic payments. A classical-contract view would not be consistent with ultratraditional views emphasizing the sanctity of marriage, requiring specific performance, and creating *inalienable* rights.

Alternative approaches to expectation damages in ancillary relief tend to be based on partial views of social welfare. Feminist writers reject divorce rules that reinforce the dependency of women on men. Unfortunately, there is a real danger of lowering the welfare of women as a consequence of the push for independence. Of course, if one wanted to deter traditional marriage, undercompensating divorced traditional wives would do just that (Cohen 1987; Cohen and Wright 2011). Not all feminist writers in family law share the same views. Kay (1987) argues for measures to increase equality between males and females in their social roles. Others (Gilligan 1982) argue that men and women are different (women’s art, women’s ways of seeing, women’s writing, and so on). Moves in divorce law to compensate spouses for career sacrifices have been sympathetically received by these groups, but actually give less-than-expectation damages, such as reliance or restitution (Trebilcock 1993). Such moves have been influential in the case law and legislation of several countries (Ellman 2007).

Modern Marriage and Unmarried Cohabitation

Separating awards of ancillary relief in divorce litigation from the issue of breach of contract is highly likely to encourage opportunistic behavior. However, for some commentators (e.g., Ellman 2007), expectation damages in marriage contracts imply lifetime support, which conflicts with a modern emphasis on equality between spouses. Another concern is encouraging costly protracted arguments over the identification of breach, although this concern may be relevant only when the court system is run largely from public funds. Would a more contractual approach to marriage resolve or amplify these issues?

The social norms surrounding intimate relationships have clearly changed in favor of serial

marriages and, indeed, unmarried cohabitation (Almond 2006). A 2015 report shows that 40% of childbirths are now outside of marriage in the USA, split 59% to 41% in favor of unmarried cohabiting parents compared with noncohabiting mothers (US Sees Rise in Unmarried Births, *Wall Street Journal*, March 10, 2015 access at <http://www.wsj.com/articles/cohabiting-parents-at-record-high-1426010894>). Marriage rates are falling, cohabitation rates are rising, and divorce rates are rising in many countries, suggesting that the view of marriage as a lifelong commitment may not correspond with the wishes of the population at large. Legal liberalization of divorce allows people to change their minds as circumstances change and to modify marriage promises. Is a more flexible view of marriage useful?

The evolution of marital law, at least in common-law jurisdictions, shows marriage to have been heavily influenced by surrounding social norms, in a manner consistent with modern legal scholarship on “relational” contracts, which are shaped by a surrounding minisociety of norms (Macneil 1978; Williamson 1985 and Macaulay 1991; Ellman et al 2014). Brinig (2000) has developed the idea of wider governance of the family into an approach emphasizing marriage as a covenant with wider society, in which family ties do not end with events like divorce but become modified as an ongoing franchise. That is a view that allows some elements of promise to persist separately when other elements are rescinded.

One approach to flexible marital covenants might be to encourage the use of clearer marriage contracts with the possibility of enforceable modifications that could be substitutes for divorce (Jones 2006; Brown and Fister 2012). The literature on contract modifications is extremely pessimistic over the prospect of welfare gain from enforcing *mutually agreed* modifications (Jolls 1997; Dnes 1995; Miceli 2002). It is difficult to distinguish good-faith revisions from those resulting from opportunistic behavior. Consider the difficulty in marriage contracts in distinguishing between a good-faith modification reflecting changing conditions underlying the marriage and the case, with no underlying change, where a party threatens to make a spouse’s life

difficult unless new terms are agreed. Contract modifications are more likely to be welfare enhancing if, in the context of unforeseen events, (i) there was a risk and it is not clear who is the lowest-cost bearer of that risk, (ii) the events were judged of too low a value to be worth considering in the contract, or (iii) neither party could possibly have borne the risk (Dnes 1995, p. 232). Generally, the view that supporting all requested modifications is desirable is unsound: there may be undesirable long-term instability as a result. Fewer people will make contracts when they cannot be protected from opportunism.

The court can determine whether some change was foreseeable and whether the attendant risk would have been clearly allocated: for example, one’s spouse’s aging is not a reason for scooting off without making compensation. On the other hand, mutually tiring of each other would have been hard to allocate to *one* party. Generally, the focus of family litigation can be expected to remain the division of benefits and obligations on divorce. Thus, there is some interest in matching ideas of relational contracting with practical rules for courts (Scott and Scott 1998). Macneil (1978) has suggested that complex long-term contracts are best regarded holistically in terms of the promissory relation as it has developed over time. An original contract document (e.g., marriage vows) would not necessarily be of more importance in the resolution of disputes than later events or altered norms.

A relational contract may be of limited help in designing practical solutions to divorce issues unless it is possible to fashion legal support for the relational contracting process. It is a fascinating challenge to put the idea of contractual flexibility together with the persistent caution of this article over the dangers of opportunistic behavior. Many problems of dividing marital assets arise because social norms have changed but the individual marriage partners failed to match the emerging marital norm. One major issue concerns marriage-dependent older wives who are likely to have specialized in domestic activities but will now be expected to be more self-reliant upon divorce. A possible approach to settling litigation would use expectation damages to guard against

opportunism but allow the interpretation of expectation to be governed by differing “vintages” of social norms. Consideration could also be given to making prenuptial, and postnuptial, agreements between spouses legally binding, which they are not in all jurisdictions. Some tailoring of marriage might be allowed, with couples choosing between *several* alternative forms of marital contract (e.g., traditional, partnership, or embodying restitution damages on divorce). A more flexible system of marriage and divorce could operate around a statutory obligation to meet the needs of children.

Cohabitation as an Imperfect Marriage Substitute

It is still early days in relation to explaining the growth in unmarried intimate cohabitation that has occurred in many societies (Almond 2006). One line of inquiry emphasizes the lower risk of loss of lifetime welfare following out-of-wedlock pregnancy that takes effect after the 1950s as birth control improved (Akerlof et al 1996). This change may have caused dominant female behavior to switch to taking more risks in unmarried relationships, and life-cycle asymmetries may have also become less marked relative to men. The obvious increase in female labor-market participation since WWII would also tend to lower the relative benefit from being insured within a traditional marriage.

Cohabitation is treated quite distinctly from marriage across all countries. The distinction is maintained in proposals from the American Law Institute to increase the protection afforded to unmarried partners in quasi-divorce litigation. The traditional common-law position is revealed in *Marvin v. Marvin* (122 Cal. Rptr. 815 [App. 1981], which is a case in a community property state), which holds that property settlements after cohabitation depend on discernible contracts and explicit or implied trusts. The position is similar in England and other countries that derive their legal systems from English common law. Statutory reforms in Canada, Australia, and New Zealand have edged the common-law world toward the continental European position of extending

elements of family-law jurisdiction to the property settlements of unmarried cohabitants.

Is it appropriate to intervene in cohabitation arrangements that have been freely entered into by apparently rational adults (Probert and Miles 2009)? Questions can be raised about how rational or informed the parties are, and there is some evidence that many cohabitants have an erroneous view that cohabitation over a period of time leads to similar rights in law as those enjoyed by married couples (Brinig 2000). It is not clear that it is welfare enhancing as a general rule to intervene ex post in arrangements that resulted from unilateral mistake (Rasmussen and Rasmusen and Ayres 1993). If intervention were to protect relationship-specific investments, then the state would effectively be prohibiting unmarried cohabitation: it would simply be creating a further form of marriage. If the general problem is really ignorance, rather than intervene in arrangements, the state might limit its efforts to providing better information flows – as in a pilot scheme operated in 2007 in the UK. If men and women really are more equal in society, such that the life-cycle asymmetries discussed above are now much weakened, then it would be appropriate to worry less about imposing the protections of marriage upon cohabitants, who, after all, could have chosen to marry. Jones (2006) has gone so far as recommending the privatization of marriage – that is, recognition of individually tailored marriage contracts – given modern developments.

There may be firmer ground under concerns that adverse impacts on children follow from less stable relationships. Cohabitation typically dissolves more frequently than marriage. Suppose that cohabitation has grown because men can be held to marriage less easily by women, given all the social changes since the 1950s. Then choices are freely made, but subject, as ever, to constraints that alter the results of choice. It is legitimate to ask whether the characteristics of the resulting equilibrium are acceptable. Scholars such as Popenhoe (1996) and more general commentators such as Bartholomew (2006, p. 249) argue that some of the characteristics, particularly the results of growing fatherlessness for children, are not acceptable. Consideration of the external effects

of less stable relationships would lead to policies encouraging marriage rather than cohabitation: not really a basis for extending marriage-like ancillary relief rules to cohabitants.

Same-Sex Marriage

The litigation-related discussion surrounding marriage and cohabitation can be extended to same-sex relationships (Fandrey 2013). One important difference is that, whereas the heterosexual has always had a choice between marriage and cohabitation, the same-sex couple has not generally had this choice. Recently, many jurisdictions have extended marriage and divorce rights to same-sex couples. From an economic perspective, the recent extension raises the question whether same-sex marriage has the same functionality as heterosexual marriage, which seems unlikely. The question comes down to whether the spouses are subject to similar life-cycle asymmetries as those identified by Cohen (1987) for traditional couples. There must be some probability that domestic investments are made asymmetrically by one partner in some same-sex unions, just as in heterosexual union, which, if true, would suggest extending something like marriage rights to same-sex couples (Dnes 2007). However, same-sex relationships appear to be characterized by considerably greater equality compared with traditional marriage (Kurdek 2004; Weisshaar 2014). In fact, equality is positively related to relationship commitment for same-sex couples (Kurdek).

It may therefore be a reasonable objection that there are very few same-sex couples with life-cycle asymmetries comparable to those of heterosexual couples in traditional marriages, which are anyway in decline. In jurisprudence, an argument that few people are affected by a condition is not in itself dispositive of a principle. We might still wish to protect even a small number of possible victims of opportunistic behavior, and support welfare-enhancing institutions even if they just affected a few. However, standing alone, that consideration would appear to open up further

extensions of marriage, for example, allowing polygamists to marry.

A strong argument for caution over extending marriage rights to same-sex couples is given by Allen (2006, 2010), who notes the possible externality involved. The welfare of large sections of the population may be lowered by the existence of marriage forms of which they do not approve, and their welfare does count. Nonetheless, same-sex marriage may be becoming increasingly acceptable, which would weaken the effect of the externality as a limit on extending marital protection. From a welfare perspective, one can coherently argue that a loss of welfare across the population may outweigh the benefits of marital protection likely to affect very few same-sex spouses. Also, Allen's argument gives a plausible limit on extending marriage rights further. Even though some participants in polygamous relationships may be very vulnerable to opportunism from an economically dominant "spouse," there are so few polygamists that a widespread revulsion would indeed dominate as a welfare effect.

Conclusions

Sophisticated contract thinking suggests a case for an expectation-damages approach to divorce litigation encompassing ancillary relief (support obligations and asset division). This conclusion is founded on controlling the incentive for opportunistic behavior set up by the asymmetric life cycles of males and females in traditional marriages. Current divorce laws may encourage opportunistic behavior in both males and females that is predatory in nature.

The contractual view of marriage and divorce explored in this article is really a perspective that proceeds by useful analogy. Different vintages and varieties of marriage would need to be recognized in practice since few marriages are now of traditional type. The approach is also consistent with a separate system of liability for child support. Contract thinking also illuminates recent trends toward unmarried cohabitation and new forms of marriage.

²Faculty of Law, University of Antwerp, Antwerp, Belgium

Abstract

This entry provides an overview of the main economic models of settlement and litigation decisions. Starting from the basic models, as developed by Landes (*J Law Econ* 14:61–108, 1971), Posner (*J Leg Stud* (0047–2530) 2:399, 1973), and Gould (*J Leg Stud*, 279–300, 1973), we describe the evolution in literature toward the application of bargaining theory. Scholars, recognizing the existence of private information and strategic behavior, increasingly modeled the process of settlement negotiations.

Economic Modeling of the Decision to Sue or Settle

Literature concerning the economic analysis of settlement and litigation has been constantly evolving since the early 1970s of the past century. Prompted by the development of the first economic decision-making models by Landes (1971), Posner (1973), and Gould (1973), law and economics scholars have persistently researched the causes of litigation. Intuitively, one might expect that all disputes will be settled rather than litigated due to the desire to avoid substantial legal costs. Although the vast majority of disputes is resolved through settlement, a small proportion still ends up in court. By means of economic modeling, scholars have tried to identify the determinants of settlement failure.

Initially, scholars focused on the outcome of the decision-making process of rational disputants. Landes (1971) focused on criminal cases, Posner (1973) applied his framework to administrative proceedings, and Gould (1973) suggested

other applications such as labor-management disputes. The existence of a “settlement range” is at the heart of this research, which applies cooperative game theory to settlement and litigation decisions. According to this approach, a necessary condition for disputes to be settled out of court is a positive settlement range, which means the defendant’s expected loss from trial exceeds the plaintiff’s expected benefit from trial. However, this is not a sufficient condition since settlement negotiations can still break down because parties cannot agree on dividing the surplus.

Subsequently, Shavell (1982) described the two-stage nature of litigation. Before parties decide whether they will settle or proceed to trial, the plaintiff has to decide to file suit. According to Shavell (1982), a rational plaintiff will only file suit when his expected value of a trial is positive. Although the earlier articles assumed that the latter condition was always satisfied, more advanced models include strategic behavior. Even in case of a negative expected value of the lawsuit, plaintiffs may still extract a settlement offer from their opponent, due to informational asymmetries which may cause the defendant to wrongly believe that the plaintiff has a credible threat. The nature and existence of these “frivolous lawsuits” has been examined, for example, in Bebchuk (1987, 1996) and Katz (1990).

Initially, the analysis was restricted to the likelihood of disputes ending in court, rather than the successful settlement amounts. The main finding was that the critical component of settling is agreement on the likelihood of success. Although divergent estimates of the latter explained the occurrence of litigation in these models, the possible sources of divergence were not discussed. This was the purpose of the next bulk of papers, which abandoned the cooperative nature of the game. Law and economics scholars, such as Salant and Rest (1982), Ordover and Rubinstein (1983), and P’ng (1983), started including private information. While these first incomplete information models solely examined the determinants of the likelihood of settlement, Bebchuk (1984) expanded the analysis to the settlement amount.

The first asymmetric information models assumed one-sided information asymmetry and a

take-it-or-leave-it offer by the uninformed party (i.e., a screening model). Subsequently, the framework was expanded by assuming that the informed party makes the first offer (see, e.g., Reinganum and Wilde (1986)). Successively, the assumption of a take-it-or-leave-it offer was abandoned by Spier (1992), who allowed for a sequence of offers. Other authors, such as Schweizer (1989) and Daughety and Reinganum (1994), considered a two-sided information asymmetry, where both the plaintiff and the defendant are privately informed about a certain element of the game.

Most litigation models take a positivistic approach and focus on the circumstances in which settlements break down, the amount for which parties settle, how procedural rules influence the likelihood of settlement, etc. Alternatively, the normative approach of other scholars examines whether litigation *should* occur (Sanchirico 2007). At the heart of this literature lies a distinction between the social cost of litigation and the private incentive to file suit. Externalities occur, on the one hand, because the plaintiff does not take into account the defendant’s legal costs (negative externality), and, on the other hand, he does not consider the socially valuable precedents that the adjudication of his case creates (positive externality). The normative approach is considered, among others, in Posner (1973), Shavell (1981), Menell (1983), and Kaplow (1986).

The following section starts with the basic model of the decision-making process of (1) a plaintiff to file suit and (2) both plaintiff and defendant to settle or litigate. When a plaintiff files suit, disputants choose between settling the case out of court (at any time preceding a judgment) or to proceed to trial when negotiations break down. In the latter case, the dispute is resolved through a court verdict (Priest and Klein 1984).

Basic Decision-Making Model

This paragraph presents the basic economic decision-making model of litigation, as first

discussed by Landes (1971), Posner (1973), Gould (1973), and Shavell (1982). Section “[Decision to Sue](#)” elaborates on the decision to sue, while “[Decision to Settle](#)” focuses on the decision to settle.

Decision to Sue

Consider the example in which a pedestrian claims that injury was inflicted by an allegedly negligent car driver. First, the pedestrian has to decide whether or not to assert a claim. Following Shavell (1982), a rational plaintiff will decide to file suit based on the outcome of a recursively solved sequence game that weighs present costs (i.e., legal costs) against expected future benefits. When the expected value of the trial is positive (i.e., benefits outweigh costs), a rational plaintiff will file suit. For a risk neutral plaintiff, the expected value of the trial (EVT) is determined by the value of a judgment in his favor (J) discounted by the probability of winning (P) minus his legal costs (C_p):

$$EVT = (P * J) - C_p \quad (1)$$

This model assumes that the plaintiff can perfectly assess the value of the parameters included. Suppose that the plaintiff has a 60% chance of winning 20.000 euro, which equals the damages endured, such as health-care expenditures (most authors assume that in case of a verdict favoring the plaintiff, the award will be equal to his damages, which are known by the judge after trial). Furthermore, the plaintiff expects to pay 2.000 euro of legal costs (e.g., court fees and costs of legal advice). The plaintiff thus expects to gain 10.000 euro from going to court, i.e., his expected benefits (20.000 euro * 0.6) minus his expected costs (2.000 euro). Given that the expected value of trial is positive, the plaintiff has a credible threat and will therefore sue. After the plaintiff has filed suit, disputants will have to decide whether they will settle the case out of court or proceed to trial.

Decision to Settle

During the bargaining phase that elapses between the filing of the suit and the start of the trial, parties

can still decide to settle. This decision depends on the “threat values,” i.e., the plaintiff’s minimum settlement demand and the defendant’s maximum settlement offer.

The defendant’s highest settlement offer equals his expected loss from a trial minus his settlement costs (S_d). In turn, the expected loss consists of the value of an adverse judgment (J) discounted by the probability of losing (i.e., the plaintiff’s winning probability (P)) and his legal costs (C_d).

$$ELT = (P * J) + C_d \quad (2)$$

Logically, the plaintiff’s minimum settlement demand equals the expected value of a trial (see Eq. 1) plus his settlement costs (S_p). Consequently, a necessary condition for reaching settlement is $EVT + S_p < ELT - S_d$, or in other words:

$$(P * J) - C_p + S_p < (P * J) + C_d - S_d \quad (3)$$

Let us assume that settlement and litigation costs are, respectively, 500 euro and 2.000 euro for each party. Obviously, the settlement and litigation costs need not be identical for both parties, but we assume this for reasons of simplicity. The plaintiff’s minimum settlement demand will then be 10.500 euro. Faced with an expected loss of 14.000 euro at trial ((0,6 * 20.000 euro) + 2.000), the defendants’ maximum settlement offer is 13.500 euro. Consequently, parties can avoid a trial by settling for any amount between 10.500 and 13.500 euro, which is referred to as the settlement range. Logically, all the values comprised by the settlement range represent mutually beneficial outcomes.

The conditions for settlement (assuming perfect information) in Eq. 3 can be reformulated as follows:

$$S_p + S_d < C_p + C_d \quad (4)$$

Equation 4 shows that under perfect information (i.e., agreement of parties on the expected value of the judgment and the plaintiff’s likelihood of prevailing), a settlement will always be reached.

In other words, $S_p + S_d < C_p + C_d$ will always be satisfied since trials are undeniably costlier. Note that it is not necessary that parties correctly estimate the expected value of the judgment and the plaintiff's likelihood of prevailing. Rather, their estimations must be consistent. Moreover, many scholars make the assumption that settlement costs are nonexistent because they are negligible compared to litigation costs (Cooter and Rubinfeld 1989).

Divergence in Expectations

Both the decision to sue and subsequently to settle or litigate depends on litigants' expectations. The previous section demonstrated that rational and risk neutral parties will not proceed to trial since the underlying condition ($C < S$) will not be satisfied. Nonetheless, many conflicts are brought to trial. One of the reasons for the occurrence of trials stems from the assumption made in section "Basic Decision-Making Model" that litigants have equal expectations about the probability of winning (P) and the value of the judgment (J). This assumption is relaxed in the following section. We start with diverging estimates of *winning probabilities* and proceed with deviating assessments of the *value of the judgment*.

At this point, we solely focus on diverging estimates of P and J as a cause of litigation, without explaining discrepancies. These reasons for diffuse distribution of lawsuit valuations are discussed in section "Causes of Divergent Expectations."

Plaintiff's Likelihood of Prevailing

As discussed in section "Basic Decision-Making Model," settlements will always occur when parties agree on the plaintiff's probability of prevailing and the value of a judgment. However, in reality, the plaintiff's assessment of winning a trial (P_p) might and, most likely will, differ from the defendant's (P_d).

In case of divergent estimates of winning probabilities, the condition for settlement in Eq. 3 that assumed $P_p = P_d$ becomes

$$(P_p * J) - C_p + S_p < (P_d * J) + C_d - S_d \quad (5)$$

or

$$(P_p - P_d) * J < (C_p + C_d) - (S_d + S_p) \quad (6)$$

Two situations may occur. First, if the plaintiff's estimation of prevailing is smaller than the defendant's ($P_p < P_d$), the left-hand side of Eq. 6 necessarily becomes negative. In this case, the condition for settlement is always satisfied, since litigation costs ($C_p + C_d$) are higher than settlement costs ($S_d + S_p$).

If, however, the plaintiff's estimated chance of winning exceeds the opponent's ($P_p > P_d$), his likelihood of going to trial enhances (Landes 1971). Whether this will eventually lead to a trial depends on the value of the judgment and the legal costs. *Ceteris paribus*, a higher award by the court will narrow the settlement range and increase the likelihood of trial. Higher litigation costs and lower settlement costs, however, have the opposite effect. Assume that the plaintiff estimates the likelihood of a judgment in his favor at 80% (i.e., P_p), while the defendant estimates the likelihood of a judgment in the favor of the plaintiff at 30% (i.e., P_d). In this case, the plaintiff's minimum demand is 14,500 euro, while the defendant's maximum offer is 7,500 euro. Hence, parties will be unable to reach a settlement agreement.

Value of the Judgment

Not only winning probabilities (P) can diverge but also valuations of the judgment (J); for reasons, we will discuss in section "Causes of Divergent Expectations."

Ceteris paribus, divergent estimates of J result in the following condition for settlement:

$$(P * J_p) - C_p + S_p < (P * J_d) + C_d - S_d \quad (7)$$

or

$$(J_p - J_d) * P < (C_p + C_d) - (S_d + S_p) \quad (8)$$

Similar to diverging estimates of P , two scenarios are analyzed when parties have different estimates

of damages. First, if the plaintiff expects to gain less than the defendant expects to lose ($J_p < J_d$), the left-hand side of Eq. 8 becomes negative. It follows that the necessary condition for settlement will always be met, since litigation costs ($C_p + C_d$) are higher than settlement costs ($S_d + S_p$). In the opposite case ($J_p > J_d$), the plaintiff is relatively optimistic about the expected judgment and thus trial becomes a more favorable option. The occurrence of trial is dependent upon the likelihood of a plaintiff win and legal costs. *Ceteris paribus*, when the likelihood of a plaintiff win increases, the settlement range narrows and hence the likelihood of settlement decreases. Higher litigation costs and lower settlement costs have an opposite effect.

Causes of Divergent Expectations

The previous two paragraphs show that optimism ($J_p > J_d$ and $P_p > P_d$) can obstruct settlement. Naturally, the question remains *why* parties' estimations of trial outcomes may diverge, in other words, why optimism occurs. Recent models explicitly include the bargaining process. In contrast to the earlier models, they show that settlement negotiations may break down, even in case of a positive settlement range (e.g., because parties cannot agree on the division of the surplus). Three different models with perfect, imperfect, and asymmetric information are distinguished. Perfect information models (such as the basic model described in section "[Basic Decision-Making Model](#)") assume that there is no uncertainty concerning the value of damages, winning probabilities, legal costs, etc. As literature shows, deviations are possible even with perfect and identical information. This will be discussed in section "[Perfect and Imperfect Information](#)." Nonetheless, diverging assessments are usually considered a consequence of private information. Imperfect information models assume, on the one hand, that parties attach probabilities to uncertain parameters in the model. However, they have analogous insight into the distribution of these probabilities, indicating the symmetric character of uncertainty. On the other hand, asymmetric information models acknowledge that disputants assess probability distributions

based on private information, meaning that uncertainty applies to these distributions as well. Section "[Asymmetric Information](#)" elaborates on asymmetric information as a cause of optimism.

Perfect and Imperfect Information

With perfect and imperfect (or symmetrical) information, causes of divergence cannot be attributed to informational considerations. In perfect information models, there exists no uncertainty, while under imperfect information, some symmetrical uncertainty occurs about the distribution of parametric probabilities (i.e., information is incomplete). The imperfect information models assume, for instance, that neither party knows the amount a judge would award. It follows that parties will use a probability distribution function to assess the likelihood of different values of damages awarded. While some simplified models assume that J can take on two values ("high" or "low"), others consider a range of possible values. As mentioned above, the uncertainty is assumed to be symmetric, meaning that parties have the same estimate of *expected* damages because they have the same information about the judge (Daughety 2000).

Perfect and imperfect information models assume that parties' expectations can still differ due to, for instance, a self-serving estimation bias. Hence, the divergence is a consequence of a difference in opinion, *given identical information* (Lederman 1998). In this case, a trial becomes a more favorable option for the plaintiff who is relatively optimistic about either a judgment in his favor (P) or the value of the judgment (J) (Landes 1971).

The drivers of self-serving estimation bias are of a psychological rather than economic nature. In general, individuals overestimate positive outcomes attributed to personal factors (e.g., the share of credit for a collaborative task or their own driving capabilities). Accordingly, parties of a dispute are likely to estimate their winning probabilities and the value of the claim in a self-serving manner (Loewenstein et al. 1993). In their experimental study, Loewenstein et al. (1993) examine parties' divergent estimates of winning probabilities and damages, while controlling for

the information about the case (i.e., there is no private information). The authors assign the self-serving bias mainly to the concept of fairness: disputants systematically overestimate parameters in their favor because they are concerned with reaching a fair settlement, rather than predicting estimates based on actual facts. Hovenkamp (1991), among others, attributes the cognitive bias to the concept of endowment, which states that individuals are willing to pay less to obtain some entitlement compared to what they are willing to accept to forsake that same entitlement.

Self-serving estimation bias aside, other factors can explain divergent assessments in the absence of uncertainty. Examples are disputant's risk preferences or discount rates. Although most studies assume risk neutrality and identical discount rates for both plaintiff and defendant, relaxing these assumptions can cause divergence of estimates. The most important assumptions that crucially impact the outcome of the decision-making model are discussed in section "[Assumptions of the Decision-Making Model](#)."

Asymmetric Information

The absence of informational structures and bargaining processes led the early models to conclude that the occurrence of optimism is the most important reason of settlement failure. A later bulk of papers expanded the original models by including the bargaining process and accounting for asymmetrical information, which in turn led to a better understanding of settlement breakdown (Bebchuk 1984). Interestingly, many predictions based on these advanced models contradict the outcomes of earlier nonstrategic studies.

In asymmetric information models, the existence of private information causes the assessment of probabilities to differ among parties. Most models apply one-sided information asymmetry, which involves one uninformed party who attaches probabilities to different values of one unknown parameter. The other party, on the contrary, is perfectly informed. Most authors state that damages (J) are known to the plaintiff but not to the defendant, while liability (P) is known to the defendant but not to the plaintiff (Daughety 2000;

Salant and Rest 1982; Spier 1992). Furthermore, divergence in J does not only depend on the expected value of damages but also on private information about the judge, future performances of witnesses, etc. (Spier 1992). Last, some models apply asymmetric information to the aspect of legal costs (C) since the amount the opponent is prepared to spend is usually unknown.

Finally, private information does not only exist between defendants and plaintiffs but also between clients and their lawyers. This agency problem causes the attorney to maximize his own utility instead of his client's (Miller 1987; Hay 1996). For example, although a rapid settlement may be in the best interest of the client, an attorney may want to establish the reputation of a tough bargainer (Spier 1992). Furthermore, lawyers could be eager to maximize their own income by overestimating winning probabilities in order to persuade clients to go to court. The impact of fee structures plays a significant role in this agency problem (see, e.g., Emons 2000).

Assumptions of the Decision-Making Model

The goal of modeling litigation decisions is to determine under which conditions disputes are settled. Obviously, results are very dependent upon the underlying assumptions. In this section, we elaborate on the most important assumptions that can crucially affect the results of the analysis.

Bargaining Games

The first models, which were based on perfect or imperfect information, applied non-Bayesian game theory to analyze settlement decisions (Polinsky and Shavell 2007). In a cooperative game, parties explicitly or implicitly commit themselves *ex ante* to reach an efficient solution ("no money is left on the table") (Daughety 2000). Although these models generally focus on the decision to settle instead of the settlement amount, some authors state that the surplus, which is determined by the settlement range, is evenly divided. This bargaining solution is used in, for example, Gould (1973), Landes (1971), and Posner (1973).

A cooperative game setting suffices in the perfect information case. However, under private information, the game is characterized by strategic behavior, such as deception and bluffing, since it is in the interest of the better informed party to exaggerate its claim (Salant and Rest 1982). A later flow of papers therefore applied a noncooperative game theory approach to allow for strategic behavior and inefficient outcomes (Cooter et al. 1982; P'ng 1983; Bebchuk 1984). In these cases, settlement negotiations may break down even though the settlement range is positive. Instead of one single cooperative solution, multiple equilibriums can be reached.

While some scholars have used simultaneous bargaining games, others have suggested a sequential game, in which the second mover is aware of the opponent's first offer. Indeed, "the process of bargaining, however, reveals information. In particular, the uninformed disputant may try to deduce the true state of nature from the actions of his informed opponent who, in turn, may attempt to exploit his initial advantage by manipulating the flow of information" (Salant and Rest 1982). Therefore, bargaining games with multiple periods allow for a learning effect and acknowledge that the uncertain parameters are determined endogenously (Salant and Rest 1982).

Furthermore, these sequential bargaining models also differ in which party moves first. In a signaling game, the informed party makes the first offer, whereas the uninformed party moves first in a screening game. Most authors assume information asymmetry concerning the likelihood of success at trial. The defendant can assess this parameter more accurately than the plaintiff, because he holds more information about his alleged liability. Consequently, the plaintiff is the uninformed party. However, when there is uncertainty about the damages, the plaintiff is usually the better informed party.

Risk Preferences

Most models assume risk neutrality of disputants. Gould (1973), however, showed that under risk aversion, settlement will always occur if disputants agree on winning probabilities. In case one

party is risk averse and the other is a risk seeker, the solution depends on the relative curvature.

Value of the Judgment

In most litigation models, the stake of a trial, i.e., the amount awarded, is symmetrical. However, parties may anticipate different expected damages, even under perfect information, if, for example, they apply different discount rates. Furthermore, a certain judgment may have precedential value to one of the disputants (Posner 2014). Whenever there are long-term considerations (e.g., reputation), the outcome of trial does not solely consist of the monetary value of the damages (Daughety 2000).

Likelihood of Trial and Legal Costs

Basic litigation models often assumed that legal costs are fixed and exogenous. However, this assumption appears unrealistic since "[...] parties expend resources on legal research to produce arguments or favorable facts to a court or other decision-making body such as a jury or administrative agency" (Katz 1988). Furthermore, legal costs are more likely to be endogenous since parties' trial expenditures are dependent upon, among others, the stakes of the trial, their belief about winning the trial, their initial wealth, and their opponents' trial expenditures (Braeutigam et al. 1984; Choi and Sanchirico 2004; Posner 2014). In other words, the amount of money parties spend is itself the result of a noncooperative game in which they maximize the net benefits of trial (Polinsky and Shavell 2007). Analogously, estimates of winning probabilities are endogenous as well. As Gould (1973) described, winning probabilities are a function of the stakes of the case and the resources spent by each party.

Discount Rates and Court Delay

Court delay enters the settlement model since it obliges disputants to discount the expected damages. Basic models, only taking into account discounting by the plaintiff, assumed that delay decreased the value of the judgment and thus enhanced the likelihood of a settlement. However, the effect of delay on the value of J depends on the discount rate of each party. In case the defendant

invokes a higher discount rate than the plaintiff, the settlement range is impacted the most (Posner 1973). Furthermore, delay increases the plaintiff's winning probability as a consequence of diminishing quality of evidence (Vereeck and Mühl 2000). Consequently, the settlement range increases and litigation becomes less likely. Although delay increases the likelihood of settlement by reducing the stakes and the quality of evidence, an opposing effect exists because it increases uncertainty about the judgment (Posner 2014). In bargaining models, the impact of delay on the decision to settle is examined, as well as the timing of a possible settlement (Spier 1992).

Procedural Rules

Settlement models can also be used to analyze the effects of legal rules, such as trial cost allocation, on the likelihood of settlement. Under the "American rule," as applied in basic models, each party bears its own costs, whereas the loser pays all costs in a "British indemnity system" (Shavell 1982 (Shavell also discusses a system "favoring the plaintiff" and "favoring the defendant"); Bebchuk 1984; Braeutigam et al. 1984; Miller 1986; Cooter et al. 1982). "Offer-of-settlement" rules, on the contrary, allocate costs based on settlement offers: if a disputant refuses a settlement offer and is granted a lower award afterwards from judgment at trial, a compensation of the opponent could be imposed (Hay and Spier 1998; Daughety and Reinganum 1994). The effect of other procedural rules on the settlement decision has been examined as well. For example, the effect of discovery requirements and disclosure rules aimed at reducing information asymmetry (Bebchuk 1984; Cooter and Rubinfeld 1994; Hay 1994), rules on the burden of proof, and rules on alternative dispute resolution (Hay and Spier 1998).

Litigation Expenditures Under Alternative Liability Rules

Jef De Mot

Postdoctoral Researcher FWO, Faculty of Law,
University of Ghent, Belgium

Abstract

For a long time there was a widespread consensus in the literature that a comparative negligence standard imposes higher administrative

costs than a simple negligence standard and a contributory negligence standard. However, in a setting where the parties can choose their level of litigation expenditures and the litigation expenditures influence the outcome of the case, it can be shown that none of the negligence rules unambiguously leads to higher expenditures. Which rule creates larger expenditures strongly depends on the quality of the case (taking into account both the defendant's negligence and the plaintiff's negligence).

Introduction

Law and economics scholars have long debated the efficiency benefits of different negligence standards, mainly simple negligence, negligence with a defense of contributory negligence, and negligence with a defense of comparative negligence. Under a simple negligence rule, the injurer is liable if and only if his/her level of precaution is below the legal standard regardless of the precaution level exercised by the victim. Under a rule of (negligence with a defense of) contributory negligence, the negligent injurer escapes liability by proving that the victim's precaution fell short of the legal standard of care. Comparative negligence divides the cost of harm between the parties in proportion to the contribution of their negligence to the accident. A lively debate exists even to date as to whether comparative negligence or contributory negligence provides better incentives to adopt optimal care (see, e.g., Artigot i Golobardes and Pomar 2009; Bar-Gill and Ben-Shahar 2003). Whereas the efficiency-promoting aspects of various tort standards remain a controversial matter, for a long time there was a widespread consensus that a comparative negligence standard imposes higher administrative costs than a simple negligence standard (Landes and Posner 1987; White 1989) or a contributory negligence standard (Shavell 1987; Bar-Gill and Ben-Shahar 2001). White (1989), for instance, argues that a comparative negligence standard likely generates higher litigation and administrative costs than contributory negligence because courts must assess the degree of

negligence by both parties and not just whether the parties were negligent. Recently, De Mot (2013) has argued that this wisdom clearly applies to settings involving fixed litigation costs but does not hold in a more realistic setting where the parties can choose their level of litigation expenditures and the litigation expenditures influence the outcome of the case (recent contributions to the economic literature on litigation stress the importance of treating litigation expenditures as endogenously determined. See Sanchirico (2007)). In the next sections “Expenditures Towards Establishing Negligence on Behalf of the Defendant,” “Expenditures to Determine Negligence on Behalf of the Plaintiff,” and “Total Expenditures and the Merits of the Claim,” I compare the influence of the three negligence rules on expenditures in an intuitive, nonformal way. I first compare the expenditures towards establishing negligence of behalf of the defendant (section “Expenditures Towards Establishing Negligence on Behalf of the Defendant”) and the plaintiff (section “Expenditures to Determine Negligence on Behalf of the Plaintiff”), after which I examine the total expenditures and how these vary with the quality of the case (section “Total Expenditures and the Merits of the Claim”). Section “Conclusion” concludes.

Expenditures Towards Establishing Negligence on Behalf of the Defendant

The litigation investments in determining negligence on behalf of the defendant are the highest under simple negligence, the lowest under contributory negligence, and somewhere in between for comparative negligence. Legal expenditures are highest under simple negligence because, unlike under contributory and comparative negligence, the plaintiff does not run the risk of being held liable himself. By contrast, when contributory and comparative negligence standards apply, the possibility that the plaintiff will be held liable reduces the expected benefit of the expenditures devoted to establishing negligence on behalf of the defendant. Intuitively, the value of spending additional resources on determining negligence

by the defendant is lower under contributory and comparative because some (or *all* in the case of contributory negligence) of the damage is shifted to the plaintiff if the latter is held liable as well.

Next, the expected value of expenditures on determining the defendant’s negligence is lower under contributory negligence than comparative negligence. There are two reasons for this. First, (only) under contributory negligence, expenditures into establishing negligence on behalf of the defendant have absolutely no value when the plaintiff is also found negligent. Second, additional investments may convince the court to conclude that the defendant’s negligence is relatively large (or small). Under contributory negligence, the degree of negligence doesn’t matter for the ultimate division of the loss. Under comparative negligence, however, it matters a great deal, because the relative degree of negligence influences the division of the loss.

Expenditures to Determine Negligence on Behalf of the Plaintiff

The expenditures to determine negligence on behalf of the plaintiff are obviously lowest under simple negligence. Under this rule, expenditures towards establishing negligence on behalf of the plaintiff equal 0 – since a simple negligence standard does not inquire into the care level of the plaintiff. The expenditures can be either larger or smaller under comparative negligence than under contributory negligence. Because the expected value of expenditures to establish or rebut a plaintiff’s negligence is lower under comparative negligence than contributory negligence, the expenditures can be smaller under comparative negligence. That is because, if the plaintiff is held liable under contributory negligence, he or she bears the entire loss; whereas under comparative negligence, a plaintiff who is held negligent only bears part of the losses (if the defendant is also held negligent). On the contrary, the expenditures can also be larger under comparative negligence because under that rule additional investments can lead the court to conclude that the plaintiff’s fault is relatively small (or large).

Total Expenditures and the Merits of the Claim

In a model with fixed expenditures, legal expenditures will always be larger under contributory negligence than under simple negligence since there are more issues for the court to decide under the former rule. However, in a model where litigation expenditures are endogenous, the total costs may be either lower or higher under a contributory negligence standard. While under simple negligence there are no expenditures to determine negligence on behalf of the plaintiff, the expenditures to determine negligence on behalf of the defendant are larger under this rule than under contributory negligence. Similarly, total trial expenditures can either be higher or lower under comparative negligence than under simple negligence.

Finally, are total trial expenditures always lower under contributory negligence than under comparative negligence? Whether the total expenditures are smaller under a comparative negligence standard than under contributory negligence depends on the relative strength of the issues. The stronger (weaker) the plaintiff's claim (taking both the defendant's and the plaintiff's behavior into account), the more likely it is that the expenditures will be smaller (higher) under comparative negligence than under contributory negligence. The intuition is the following. First, when the actual degree of fault of the defendant increases, the importance of the outcome of the issue of the plaintiff's negligence increases under both rules but more so under contributory negligence than under comparative negligence (because of the all-or-nothing character of contributory negligence). Second, when the actual level of fault of the plaintiff decreases, the importance of the outcome of the issue of the defendant's negligence increases under both rules but more so under contributory negligence than under comparative negligence (due to the sharing element of comparative negligence). Third, the greater the difference between the true levels of fault of the parties, the smaller the value of

investing in trying to convince the court that one's level of fault was more modest. The effects of such investments are more heavily discounted when the difference between the levels of fault is relatively large. A simple example can illustrate this. Suppose we can represent the level of fault of the plaintiff by the number 0.2 and the defendant's level of fault by the number 0.8 and that the court uses the following formula to determine the plaintiff's share: $0.8/(0.8 + 0.2) = 0.8$. Now suppose the defendant can make an investment i that will reduce his level of fault (as ultimately perceived by the court) with 0.1 ($0.8 - 0.1 = 0.7$). Then the plaintiff's share would equal $0.7/(0.7 + 0.2) = 0.78$. Now we look at a case in which the levels of fault are more close: 0.5 for the plaintiff and 0.8 for the defendant. The plaintiff's share will be $0.8/(0.8 + 0.5) = 0.62$. Clearly, the investment i , which again reduces the level of fault of the defendant with 0.1, has a greater payoff for the defendant in such a closer case: $0.7/(0.7 + 0.5) = 0.58$. So here we get a reduction of 0.04, while in the previous case the reduction was only 0.02. Clearly, there will be more investment in the latter type of cases.

Conclusion

When litigants can choose their level of litigation expenditures and these expenditures influence the outcome of the case, none of the negligence rules unambiguously leads to higher expenditures. Which rule creates larger expenditures strongly depends on the quality of the case, taking into account both the defendant's negligence and the plaintiff's negligence.

Mafias

Guglielmo Barone¹ and Gaia Narciso²

¹Bank of Italy and RCEA, Bologna, Italy

²Trinity College Dublin, Dublin, Ireland

Abstract

Organized crime has far reaching economic, political, and social consequences. This entry presents the basic facts on the economics of mafias, with a special focus on the Sicilian case that may serve as a window into other types of criminal organizations. First, the entry provides a brief sketch of the theoretical modelling of the mafia. Then, it reviews the theoretical and empirical work testing the role of geography in the historical origins of the mafia. Finally, the entry explores the economic impact of the mafia in terms of missed opportunities of development, both in the short and in the long run. Different transmission channels are explored.

Definition

A secret and criminal organization which is engaged in a number of illicit activities such as racketeering, smuggling, trafficking in narcotics, and money laundering. It has a complex hierarchical organization, and its members are expected to follow a number of internal rules. The mafia

originated in Sicily in the second part of the nineteenth century and expanded to the United States through Italian emigration. Nowadays, mafia-type organizations are widespread in many countries, especially in Southern Italy, Russia and East Europe, Latin America, China, and Japan.

Introduction

Organized crime entails deep economic, political, and social consequences. Its presence is pervasive and threatens the functioning of democratic institutions (Allum and Siebert 2003; Bailey and Godson 2000; Fiorentini and Peltzman 1996). Due to its varied features and the lack of empirical data, very few empirical studies have, until recently, investigated organized crime and its impact on the economy. This emerging literature deals with different issues. Some papers focus on the theoretical framework (Dal Bò et al. 2006; Skaperdas 2001), while empirical studies investigate either the origins of mafia, stressing the role of natural resources and land value as key determinants, or its negative economic consequences. Overall, the mafia is found to have a negative impact on growth and GDP per capita; the underlying mechanism may work through lower government efficiency, lower foreign direct investment, distortions in the allocation of public funds, or unfair markets competition.

This entry presents the evidence on the economics of mafias, with a special focus on the

Sicilian case. The Sicilian Mafia is a complex phenomenon that acts, at times, within Italian institutions, at times against them. The Sicilian Mafia serves as a window into other types of criminal organizations, such as the Russian Mafia or the Japanese Yakuza (Maruko 2003), which are rooted in the political and socioeconomic spheres. First, the entry provides a brief sketch of the theoretical modeling of the mafia. Then, it reviews the theoretical and empirical work testing the role of geography in the origins of the mafia. Finally, the entry explores the economic impact of the mafia in terms of missed opportunities of development, both in the short and in the long run.

Theoretical Models of Mafia and the Analysis of Its Origins

On a theoretical ground, this entry adopts the widespread view according to which the mafia is treated as an industry that produces and sells a number of goods and services, such as private protection services, narcotics, or connections with politics (Gambetta 1993, 2000). Such a view is consistent with the historical origins of the mafia. Under this perspective, the supply of protection services plays a key role. According to a consolidated opinion, the mafia emerged in Sicily after (or around) the unification that took place in 1861. In 1876, Leopoldo Franchetti, a Tuscan intellectual, traveled to Sicily to conduct a private inquiry into the political and administrative conditions of the island. The report was published the following year and represents an original and detailed picture of the state of Sicily at that time (Franchetti 2011). The report is the first document of the issues related to the mafia and its permeation through the Sicilian society. The demand for private protection arose in Sicily for two interrelated motives. First, before Italian unification, a series of anti-feudal laws endorsed the opening up of the market for land, which led to an increase in the fragmentation of land property. Second, following the Italian unification in 1861, a weak protection of property rights and a vacuum of power from the recently constituted

State amplified landowners' need for protection against illicit expropriation. In such historical moments, the mafia emerged as an industry offering a number of services the State was not able to offer.

This theory has received robust empirical support. Some authors analyze the relationship between land fragmentation and mafia activity in the nineteenth century. From a theoretical viewpoint, in fact, it can be shown that the rise in the number of landowners (following the end of Feudalism in 1812) increased competition for protection, which ultimately led to an upsurge in mafiosi's profits. The data collected from the parliamentary survey conducted by Damiani in 1881 show that the historical presence of mafia in Sicily was indeed more likely to be found in towns where land was more fragmented (Bandiera 2003). The land fragmentation was not the only determinant of the upsurge in the mafia. The end of feudalism and the demise of the Bourbon Kingdom in the South of Italy were accompanied by a rapid increase in the demand of sulfur, of which Sicily became a major exporter between 1830 and 1850. Sulfur was used as an intermediate input in the industrial and chemical production, which was flourishing in France and England in the nineteenth century. Sulfur mines in Sicily were mainly superficial and did not need sophisticated extraction technology. By the end of the nineteenth century, over 80% of world sulfur production originated from Sicily. Consistently with the idea of mafia as the supply side of a market of protection and extortions, data on the Sicilian Mafia in the late nineteenth century (Cutrera 1900) shows that the intensity of mafia activity was higher in municipalities with sulfur mines, where the demand for private protection was higher Buonanno et al. (forthcoming). In a similar fashion, other authors have associated the origins of the mafia with the presence of citrus fruits, which were highly valuable (Dimico et al. 2012). Lemon trade between Sicily and the United States flourished: 34% of imported citrus fruits originated from Italy. This explanation of the origins of the Sicilian Mafia is indeed in line with that outlined in a parliamentary inquiry dated 1875, according to which "Where wages are low and

peasant life is less comfortable, [...], there are no symptoms of mafia [...]. By contrast, [...] where property is divided, where there is plenty of work for everyone, and the orange trees enrich land-owners and growers alike – these are the typical sites of mafia influence.”

Although the mafia historically emerged in the South of Italy, it gradually migrated to other Italian regions (and to the United States). The first main mechanism of diffusion of the mafia was the mass migration from Southern to Northern Italy, which took place between the 1950s and 1970s. It is estimated that four million people migrated from the South to the North, during the economic boom. The mass migration led to a change in the population composition of the receiving regions. As a result, mafia-type organizations were more likely to emerge in areas that were more migrant-abundant. The second mechanism of the expansion of the mafia in the North is due to the *confino* law: the imprisonment policy for mafiosi was based on the *confino*, a policy according to which mafia-related criminals were imprisoned in a different region from the one they originated from, in order to loosen the links with the local mafia. However, the *confino* had the perverse effect of spreading mafia activity in other Italian regions (Varese 2006, 2011).

Economic Consequences of Mafia: GDP Growth

Besides analyzing the origins of mafia, economists also examined its consequences in terms of economic growth, together with the potential underlying mechanisms. This is the second main strand of the economic literature on organized crime. Assessing the economic impact of mafia activity suffers from two main issues. The first issue is concerned with the lack of data. Only recently, new data on criminal activities have been made available. However, even where available, data on crime often suffer from measurement error. For example, the number of crimes could be underreported, in particular in relation to specific categories. Second, and more severely, analyzing

the impact of mafia activity on the economy implies knowing how the economy would have been in the absence of mafia activity. However, a country or a region is either mafia-ridden or not (this is known as the fundamental problem of causal inference); therefore, it is very difficult to have a credible counterfactual. A convincing way to tackle this issue is to adopt the synthetic control method, a methodology that has been recently proposed to statistically examine comparative case studies. This methodology has originally been introduced to estimate the effect of the Basque conflict on GDP per capita (Abadie and Gardeazabal 2003). Later, it has also been applied to estimate the impact of the mafia in two Southern Italian regions – Apulia and Basilicata – which experienced a surge in mafia activity starting over the last few decades. Until the 1970s, these two Southern regions had witnessed little or no mafia activity in their territory. Starting from the 1970s, mafia activity and its connected violence rapidly increased in these two regions. A counterfactual is constructed using the information related to other regions where the mafia has been absent throughout the period considered. Mafia activity emerged in Apulia and Basilicata following three relevant episodes. First, the profitable activity of tobacco smuggling led to a ferocious conflict among different criminal groups. Second, the earthquake that struck the area between Campania, Basilicata, and Apulia in 1980 was followed by a flow of public funding for the reconstruction of the area. The increased availability of public funding led to an increase in mafia activity, attracted by the opportunities of grabbing a portion of these funds. Finally, the imprisonment policy for mafiosi was based on the *confino*, the policy according to which mafia-related criminals were dislocated in a different region from the one they originated from, in order to loosen their links with the local mafia. Apulia had the highest number of criminals according to the *confino* policy, which led to the spread of mafia activity in Apulia. The impact of mafia organizations on economic growth appears to be very significant. According to the synthetic control estimates, mafias are responsible for a 16% loss in GDP per capita over a 30-year period Pinotti (forthcoming).

Economic Consequences of Mafia: Misallocation of Public Funds

Such a huge impact captures the reduced-form causal effect from the mafia to GDP. Researchers have also devoted their efforts to highlight the underlying transmission mechanisms. One relevant channel consists of the misallocation of public funds (Barone and Narciso 2015). The case study regards the Italian Law 488/92, which has been the main policy used by the central government to promote growth in the southern Italian regions, by offering a subsidy to businesses investing in underdeveloped areas. Even though the law governing funding allocation had very detailed provisions to distribute subsidies, aimed at reducing the risk of fraud, many investigative reports state that the mafia managed to circumvent these criteria. A number of accounting and financial mechanisms have been used to divert funds, such as the creation of made-up firms, i.e., firms set up with the only scope of applying for public subsidies. Moreover, the mafia was able to corrupt public officials involved in the allocation of funds. By combining information on the spatial distribution of Law 488/92 funds with that of mafia activity, the study investigates whether mafia presence is able to influence public funds' allocation. The endogeneity of the link between the mafia and public funding must be addressed, in order to provide a causal interpretation to their relationship. Endogeneity may arise due to measurement error, omitted variables, and reverse causality. Instrumental variable identification strategy is a proper way to deal with the endogeneity issue. Focusing on Sicily, it is possible to construct a credible instrumental variable that is conceptually based on the historical origins of the Sicilian Mafia. As stated above, around the Italian unification in 1861, the demand for private protection arose in Sicily for two main motives. First, before the country's unification, a series of anti-feudal laws led to the opening up of the market for land, which contributed to the division of land property. Second, the vacuum of power following Italian unification and lack of protection of property rights amplified

landowners' need for protection against expropriation. The Sicilian Mafia arose as an industry offering private protection in this specific historical juncture. Indeed, in line with the literature on the origins of the mafia presented above, the mafia was more likely to appear in areas where the land was more valuable. Consequently, historical and geographical measures of land productivity can be used as instrumental variables for current mafia activity. In particular, the set of instruments includes rainfall shocks in the nineteenth century and geographical features (e.g., altitude and slope). This empirical strategy suggests that mafia presence has a positive effect on the likelihood of obtaining funding and the amount of public transfers: according to the existing estimates, mafia presence raises the probability of receiving funding by 64% and increases the amount of public funds to businesses by more than one standard deviation. The results are robust to different econometric specifications and to the use of alternative measures of the mafia. The mafia has a positive causal effect on public subsidies, but how should this result be interpreted? For example, is the positive relationship between mafia presence and public transfers due to a more generous public spending towards mafia-ridden areas? A falsification test suggests that the answer is negative: these areas display a lower level of expenditure on culture and education, in comparison to those where the mafia is absent. Were the State more generous towards disadvantaged areas, presumably it would have spent on other budget categories, such as education or culture. Moreover, there is empirical evidence on the mechanism through which the mafia can determine the allocation of public resources: the mafia is used to make connections with local entrepreneurship, and its presence raises the number of corruption episodes in the public administration sector. The impact of the mafia can also be disentangled from that stemming from a more general criminal environment. In the end, by diverting public subsidies assigned to poorer areas, the mafia hampers growth, investment, and, ultimately, development. From this perspective, this finding provides a relevant contribution

to the debate on the desirability and the design of public subsidies to firms.

Economic Consequences of Mafia: Other Channels

The impact of mafia organizations has been found to also affect the bank credit market. Using data on bank-firm relationships, it has been shown that crime has a negative effect on access to credit in Italy. Borrowers in high-crime areas pay higher interest rates and pledge more collateral. These results are found to be driven, in particular, by mafia-related crime, extortion, and fraud. By distorting loan conditions to firms, mafia organizations indirectly negatively affect investment and growth in the long run.

The effect of mafia on the economy can also work through the public sector. Organized crime usually operates as a pressure group that uses both bribes and the threat of punishment to influence policy. Consistently, on the empirical side, one can observe that criminal activity before elections is correlated with lower human capital of elected politicians and an increased probability that these politicians will be later involved in scandals. However, a strict legal institutional framework can contrast this bad influence. In the Italian case, when the central government imposed the dissolution of municipal government because of mafia infiltration, the quality of local politicians (proxied by their average education level) significantly improved Daniele Geys ([forthcoming](#)).

Finally, organized crime hinders fair market competition because mafia-related firms, which are usually run to launder money, can operate under the break-even point, thus forcing legal competitors out of the market; mafia also represents a deterrent for foreign investors, so depressing foreign direct investment.

Manne, Henry

Enrico Colombatto

Università di Torino, Turin, Italy

IREF (Institut de Recherches Économiques et Fiscales), Lyon, France

Abstract

This entry illustrates the very prominent role Henry Manne played in the Law and Economics tradition. Manne made seminal contributions in two key areas: the dynamics of corporate control, and the ethics and efficiency of insider trading. He showed that the market for corporate control is an efficient way of protecting shareholders' interests and restraining abuse by the managers. From a normative standpoint, he emphasized that no specific regulation is required in these areas. The same normative conclusions also apply to insider trading, which is the quickest way of circulating information and avoiding bubbles. This entry concludes by summing up Manne's contributions in education.

Biography

Henry Manne (1928-2015) deserves a very prominent place among the founding fathers of Law and Economics, along with Guido Calabresi and Ronald Coase. In particular, since the late 1950s, Manne applied economic reasoning to investigate policy issues in two key areas that had previously been considered as the exclusive object of legal analysis: the dynamics of corporate control, and the ethics and efficiency of insider trading. In both cases, and despite considerable initial skepticism, Manne's contributions radically changed the way the economic and legal professions have regarded these topics. Furthermore, and typical of his vision, he used the law-and-economics approach to show that regulating the life of the corporation is unjustified and possibly harmful.

Manne (1962) and Manne (1965) are the path-breaking articles that opened new research

agendas in the economics of the modern corporation. In his 1962 contribution, Manne took on the traditional argument according to which small shareholders have little incentive to monitor the managers' behavior and actively partake in the life of companies. In particular, the traditional argument held that regulation is required in order to force the managers to disclose the information shareholders need, to enhance shareholders' participation, and to restrain the managers' potential abusive behavior. By contrast, Manne argued that the market for corporate control is effective in protecting the shareholders' interests, regardless of how much time and efforts they devote to monitoring the managers. If the managers misbehave, the value of the company declines, outsiders will be interested in buying the shares, gaining control and replacing the inefficient executives. In other words, in Manne's view, the market for mergers and takeovers ensures that share prices cannot drop for long because of managerial slack, as long as outside buyers are allowed to intervene and buy shares to obtain control. Indeed, the threat of a takeover is already enough to prevent the shareholders from being injured: if the incumbent managers fear the consequences of a hostile takeover, they are likely to react by improving their performance and meeting the incumbent shareholders' expectations. If so, performance improves and share prices recover. Once again, shareholders are protected, and share prices stay close to the company's true value. Therefore, Manne concludes, under both circumstances there is no need for regulation/legislation: Competition is indeed effective in keeping the managers under pressure and shielding small investors from abuse. By contrast, regulation frequently ends up defending the managers and justifying redistributive activities that have nothing to do with the purpose of the modern corporation.

Manne (1965) develops his earlier insights by moving from analyzing the relationships among shareholders and managers, to studying the economics of mergers. A takeover takes place when company A buys shares from company B's shareholders. It is an operation that prevents B from going bankrupt and that can be

completed in three different ways: proxy fights, direct purchase and mergers. As mentioned, Manne focuses on mergers, the buyers' preferred course of action, since they do not need to collect cash to finance the operation and they can skirt taxation. Not surprisingly, in these cases, corporate statutes play a crucial role in determining the outcome. For example, mergers usually require qualified-majority voting and can hardly succeed if B's incumbent management owns a relatively large portion of B's shares. Thus, one should not be surprised if company A and company B managers end up colluding. Under such circumstances, the merger would then take place with the consent of the management. This is still a desirable outcome: the top executives would be forced to exchange information, which promotes efficiency. As a result, according to Manne the frequent concerns raised by the antitrust authorities are misplaced: mergers are the result of a healthy, free-market, welfare-enhancing environment, rather than a threat to competition or to shareholders' interests.

Innovative and Original Aspects

Insider trading was the object of Manne (1966), a book that was actually his J.S.D. dissertation thesis at Yale and ignited a debate still lively today. In contrast with the views that dawned at the beginning of the twentieth century and became dominant since the mid-1930s, Manne made two key arguments. First, insider trading is a form of compensation for the managers and employees at large. It is cheaper than other forms of remuneration, and provides sets of incentives that contribute to bringing together the interests of the managers, the entrepreneurs and the owners. Second, insider trading is efficient, since it represents the quickest vehicle to circulate information, and reduces the risk of bubbles. In other words, insiders have accurate information about the company where they work, they ensure that this information is immediately available to the ordinary shareholders, and perform better than the regulators. Hence, legislation designed to curb insider trading is ineffective, harmful, and ethically

questionable, since it punishes an alleged crime in the absence of victims.

Impact and Legacy

Manne's work left a lasting legacy in two other areas: teaching and the economics of higher education. Manne was not only a great scholar, but also a determined and successful intellectual entrepreneur. As detailed in Manne (1993), while serving as a Professor at the University of Rochester, he started planning a new type of law-school curriculum, which emphasized the need for specialization, but at the same time required a cross-disciplinary approach to the selected area of specialization. While still in Rochester, in 1971 Manne launched an intensive summer course in economics designed to suit the needs of law professors. In 1974, Manne moved to the Miami Law School, where the program became the Law and Economics Center at the University of Miami, and offered economics courses to federal judges, too. Later, the Center moved to Emory and then in 1986 to George Mason University, where Manne was heading the Law school and eventually put in practice the innovative curriculum he had drafted in Rochester. These programs were an impressive success: they contributed to the professional life of generations of lawyers, law professors and judges, and made a real difference in the way the legal profession regarded economic issues, in the classroom and in court.

Manne (1973) is perhaps his best-known contribution to the understanding of the nature and dynamics of modern universities. Although focused on the American experience, much of Manne's arguments also apply to the academic environment prevailing in Europe. In particular, Manne drew attention to the consequences of an academic context characterized by extensive funding by governments and governmental agencies, foundations and companies, and in which the role played by the students' fees is modest. This setting has ensured that modern universities are less and less answerable to their clients (students). Put differently, Manne claimed that public funding has ensured that tenured professors are

all but unaccountable, and tend to pursue their own interests (mainstream research and consultancy), rather than meet the educational needs of their students, transfer knowledge, and help them develop critical abilities and creative thinking. Moreover, by making students and public opinion trust the virtues of educational establishments as heavily subsidized, not-for-profit organizations, faculties have succeeded in transforming modern universities into stable systems where intellectual entrepreneurship remains marginalized. According to Manne, in order to ensure stability, hiring procedures frequently reward scholarship accomplishment (mainstream research agendas, which do not necessarily imply scholarly value), and favor candidates who guarantee loyalty to the incumbents and feature nonmarket attitudes. The upshot is an ongoing decline in the quality of education, with very few exceptions, on both sides of the Atlantic.

Market Definition

Javier Elizalde

Department of Economics, University of Navarra, Pamplona, Navarra, Spain

Abstract

The goal of this essay is to explain the role attributed to the analysis of market definition in the guidelines which rule in the United States and the European Union and to revise some of the empirical tests proposed by researchers in the fields of competition Economics and Law along with some of the critiques they received regarding their applicability for antitrust purposes.

Definition

Market definition is the analysis of determining the products which compete with each other and the geographic area where that competition takes place. The attention is paid, on one hand, to the concept of substitution among potential competitive products and, on the other, to the existence of joint market power by the firms which operate in the market especially for antitrust purposes.

Introduction

Market definition consists on the delineation of the market boundaries in the product and geographic dimensions from a competitive perspective. The interest for the researchers in the field of Law and Economics has led to the formulation of empirical tests of market definition, and much discussion has arisen mainly regarding their

compatibility with the market definition test which rules in the US antitrust legislation for merger control, known as the “hypothetical monopolist” (or SSNIP) test. The analysis of market definition has been performed under two alternative (not necessarily incompatible) purposes. First, in the tradition of Marshall (1920), the market comprises all the goods which are substitutes so they should exhibit identical prices with differences due to transportation costs. This approach is most plausible when the goal of the analysis is to find the geographic market for a homogeneous good. The second approach is to identify the products and the geographic area such that the firms who serve them may jointly enjoy substantial market power without relevant competitive constraints from other products or areas regardless of whether the other alternatives can be considered substitutes from the consumer perspective.

Market Definition in Merger Control

The market power approach has become predominant for researchers in the field of Law and Economics since the publication of the Horizontal Merger Guidelines in 1982 by the US Department of Justice (see Department of Justice and Federal Trade Commission (2010) for the latest revision). They introduced the hypothetical monopolist test of market definition. The rationale for this test is that the relevant market should include all those products and the geographic area such that, if they were all owned by a single firm (the hypothetical monopolist), the latter would enjoy some market power, being able to profitably exercise a “small but significant and non-transitory increase in price” (the initials SSNIP are used when referring for a price increase with that feature). This means that products other than those forming the relevant market do not impose a significant competitive constraint. The text mentioning the hypothetical monopolist test has been modified in the revisions of the horizontal merger guidelines of 1984, 1992, and 2010, but the role attributed to market definition as a preliminary and screening process in the investigations of competitive effects of mergers prior to the calculation of market shares

remains. Market definition is a previous step to the assessment of market power which is the main concern of antitrust authorities when investigating mergers.

In the European Union, there is no test which must be used for market definition. The concept of a relevant market was established in the 1997 “European Commission Notice on the definition of the relevant market for the purposes of Community competition law” and relies on the concept of consumer substitution “[...] by reason of the products’ characteristics, their prices and their intended use.” The definition of a relevant market ruling in the European Union includes both demand-side and supply-side substitutes when substitution takes place “quickly and easily.” The Notice mentions a version of the hypothetical monopolist test as a suggested method and enumerates a series of econometric tests, which are actually detailed in the following paragraphs of this essay.

Empirical Tests of Market Definition

Regarding the empirical literature on market definition, the earliest works were mainly intended to identify the geographic market for a homogeneous good. An approach which was dominant for geographic market definition before the attention was led to prices was the Elzinga-Hogarty test (after Elzinga and Hogarty 1972, 1973) which was a test of shipment data. It used aggregate inflows and outflows of consumers to determine market boundaries. Geographic market boundaries were expanded until both flows were below a cutoff level. This test was used for analysis of hospital mergers in the United States in the 1980s and 1990s, and it received many critiques especially for the limitation of the test to account for the heterogeneity of patients to travel for medical care.

Both in the fashion of the Marshallian concept of a market of equal prices and on the emphasis on the ability to increase prices stated in the US guidelines, the tests of market definition became primarily tests of price data or both prices and quantities when data were available.

There is a vast stream of literature on market definition using tests of time series of prices. Stigler and Sherwin (1985) proposed a test based on price *correlations*. Under the prior that the differences in prices of products of the same market are due to transport costs, their price movements must follow the same pattern so the time series of those prices must be correlated.

Horowitz (1981) suggested that the Marshallian prediction of equality of the prices only occurs in equilibrium. When shocks happen, there are adjustment lags before returning to equilibrium. Horowitz proposed a test called the *speed of adjustment* test as it is focused on estimating the speed at which the short-term difference in prices between two areas returns to the long-term difference. A persistent divergence between the short-term difference and the long-term difference would mean that the two products or areas are in different markets.

Another test called the *causality* test includes products in the same geographic market if the long-run difference between price series is independent of exogenous influences not related to costs. The test, proposed by Uri and Rifkin (1985) and Uri et al. (1985) and based on the concept of Granger causality, defends that the price in one area of a geographic market could be predicted with information on prices in the other area.

Slade (1986) proposed an *exogeneity* test according to which, if a disturbance in one area spills into another area, the exogeneity of price formation is rejected and both areas are in the same market.

A *stationarity* test of market definition was performed by Forni (2004) analyzing the long-run price ratio between two areas rather than a series of short-run price differences which were used in previous tests. Using this test, if the long-run proportional relationship between the prices in two areas is not stationary, then the areas can be said to be in different markets.

On the grounds of market definition related to substitution between products for the consumer, much work has relied on elasticities of demand when data on both prices and quantities has been available. The own-price elasticity of demand provides information on the existence of

substitutes for a good, and the cross-price elasticity of demand between two goods provides information on whether those two goods are substitutes, which would be the case if it takes a positive value. A noteworthy approach is the analysis of critical elasticity and critical loss, following the works by Johnson (1989) and Harris and Simons (1989). The main focus of this analysis is the own-price elasticity of demand of the hypothetical monopolist. The critical elasticity is the maximum elasticity of demand a hypothetical profit-maximizing monopolist could face at pre-merger prices to be able to profitably increase its price by a SSNIP. If the elasticity faced at pre-merger prices is higher than the critical elasticity, the hypothetical monopolist would not raise profits with that increase in price so this would lead to market aggregation. The critical loss is the maximum reduction in output a hypothetical monopolist can tolerate in order for the increase in price to be profitable. If the actual loss is higher than the critical loss, the price increase is not profitable, so the relevant market should be expanded.

An alternative approach is based on the own-price elasticity of the residual demand of the hypothetical monopolist. Baker and Bresnahan (1988) used this methodology to estimate the degree of market power in an industry with differentiated products (the beer industry in the United States). Scheffman and Spiller (1987) applied it to the geographic market definition for a homogeneous good (unleaded gasoline in the Eastern United States). Once the value of the own-price elasticity of the hypothetical monopolist's residual demand is estimated, the effect of the price increase on the monopolist's profit is computed (see also Kamerschen (1994), Ekelund et al. (1999), and Cardona et al. (2009) for other works under this approach).

The recent emergence of detailed retail data on prices, quantities, and other variables (often through scanner systems) has favored the estimation of each firm's individual demand, and, through the estimation of both own- and cross-price elasticities of demand, the likely effects of mergers can be simulated. Some works use this methodology for the definition of the relevant market for cars (Brenkers and Verboven 2006,

analyzing competition at both the manufacture and retail levels), computer servers (Ivaldi and Lörincz 2011), and movie theaters (Elizalde 2013, which analyzes both demand-side and supply-side substitution).

There is a vast literature, such as Werden (1990, 1998, 2003), Werden and Froeb (1993), O'Brien and Wickelgren (2003), and Hosken and Taylor (2004) among many others, which criticizes most of the tests enumerated above by showing their incompatibility with the hypothetical monopolist test of the US guidelines and their invalidity for predicting the likely effects of mergers, as some of the tests are intended to the identification of substitutes or are based on past evidence with limited capability to predict future events among other reasons.

Coate and Fischer (2008) provide a review of the tests employed by the enforcement agencies in the United States along with comments about the works which proposed them and the critiques they received.

Controversy Regarding Market Definition

Market definition itself, especially with the role attributed in the US antitrust legislation, is strongly criticized in some grounds of Law and Economics which are very much skeptical about the competition authorities' interest on market concentration and market power, as the immediate usefulness of market definition is the calculation of market shares. Coinciding with the 2010 revision of the US Horizontal Merger Guidelines, an alternative to market definition, based on the upward pricing pressure (UPP) resulting in a merger, was proposed by Farrell and Shapiro (2010) and critically discussed by Carlton (2010), whereas Kaplow (2010, 2011) defends the elimination of market definition as conclusions may be misleading.

Market Failure: Analysis

José Luis Gómez-Barroso
Dpto. Economía Aplicada e Historia Económica,
UNED (Universidad Nacional de Educación a
Distancia), Madrid, Spain

Abstract

Given that there is no agreement on the procedure by which economic efficiency should be measured, a closed catalogue of market failures cannot be talked about. There is however a reasonable agreement in economic literature on the identification of up to a total of five reasons for the existence of market failures:

public goods, externalities, imperfect competition, information failures, and incomplete markets. There are three other situations that some authors also include in the list of market failures: merit goods, an unbalanced macroeconomic situation, and economic situations that assault criteria of equity.

Definition

Market failure is any situation in which the autonomous action of the market does not lead to an economically efficient outcome.

Introduction

Drawing the border between public and private is and has been a constant concern throughout the history of human thought. The economy is one of the fields in which such a distinction is vital. In this discipline, whatever space there is for what is public is derived from the answer to a basic question that every economist has faced: does the joint action of individual agents in pursuit of self-interest (utility or “happiness” in the case of individuals; benefit in the case of entrepreneurs) cause an acceptable result from the point of view of the common interest? When the answer is no, public intervention to correct such situations could be admissible. The unacceptability of the result of private activity derives from the use of equity or efficiency criteria. In this second case, that is, when the market does not lead to an efficient outcome of its own accord, it is said that we are in the presence of market failure.

Given that there is no agreement on the procedure by which economic efficiency should be measured (not even on the actual definition of the concept of efficiency), a closed catalogue of market failures cannot be talked about. Consider that some school of economic thought even denies their existence. Nor is there consensus on what should be done (or even whether anything should be done) to correct market failures.

By dint of being an entry in an encyclopedia proceeds to adopt a nonrestrictive approach, and

the following section describes all the circumstances in which the existence of a market failure has been reasonably argued. There is insistence on the fact that many currents of economic thought would reduce the list and would furthermore qualify the extension that should be given to each type of market failure. In this respect, the definitions given are the most repeated and accepted, though for each market failure there is an extensive bibliography that would enable each of the concepts to be specified, formalized, or criticized.

Types of Market Failures

There is a reasonable agreement in economic literature on the identification of up to a total of five reasons for the existence of market failures. They are not mutually exclusive or even independent. For the purposes of classification, they can be regrouped into two blocks:

- Those linked to the characteristics of the activity or of the good in itself: public goods and externalities
- Those related to the market situation: imperfect competition, from which information failures can become independent, and incomplete markets

There are three other situations that some authors also include in the list of market failures, though this is not the norm in literature:

- Merit goods
- An unbalanced macroeconomic situation (existence of unemployment, waste of resources)
- Economic situations that assault criteria of equity

Intrinsic Characteristics of the Good or Activity

Public Goods

There are two characteristics that define a public good: it is non-excludable and consumption is non-rivalrous. In other words, no one can be

deprived of enjoying the good and its consumption by an individual does not exhaust it or even affect the utility that others can extract from its consumption. The most typical examples that are mentioned in literature are national defense or coastal lighthouses.

“Pure” public goods that rigorously meet these two restrictions are few and far between. A large part of those considered public goods possess these attributes under certain conditions and could even be treated as private in different contexts. Moreover, the situations in which it is possible to talk about public goods are sometimes circumstantial. In a free wireless Internet area, consumption is non-rivalrous, as long as there are no agglomerations, but if the number of connections is excessive, “consumption” of the good by other people reduces utility and there is competition for the resources. The term impure public goods is usually used when there is a congestion problem.

With some goods, even though their underlying structure functions *naturally* as a public good, uses that break the public space in private spheres, where access is conditioned, can be developed. If a beach becomes private, a toll is set up on a motorway, or a television transmission is codified, it is evident that exclusion is possible. These situations are described as club goods.

In the case of public goods, the non-efficient outcome originates in the market not being interested in offering these goods, since in a situation of impossible exclusion income would depend on the will to contribute to their financing by those who enjoy them: how can the “right to see” a fireworks display be charged? And if exclusion can be and is actually chosen, non-efficiencies would also be generated, considering that the marginal cost of the enjoyment experienced by an additional person is zero (non-rivalrous consumption). The second reason why a non-efficient situation can be created is the overexploitation of goods that would otherwise be public. Excessive use does not only end non-rivalry in consumption, but can lead, in the extreme, to the disappearance or exhaustion of resources that are common property, such as fishing grounds or aquifers.

Nowadays, the concept of public goods has been extended from a local scale to a global scale with the introduction of the concept of global public goods. World peace, financial stability, and the eradication of epidemics would be global public goods because, once achieved, their benefits, which no one could be left out of, would be geographically unlimited. What is true is that some of these concepts, such as peace, are more desirable political objectives than goods that could be supplied by the market and, therefore, it is not strictly accurate to talk about market failures.

Externalities

There is an externality when a concrete activity influences other activities or individuals that do not directly participate in the first activity. Externalities can be positive, if this spillover is beneficial, or negative, if they cause harm. The most typical examples collected in literature are, respectively, fruit trees pollinated by bees from a nearby apiarist and the contamination of a river.

In the presence of externalities, a social cost should be added to the internal cost reflected in a company's bookkeeping. The opening of several drinking bars in a specific neighborhood may favor certain businesses in the area (car parks, takeaway restaurants), but may have a negative effect on local residents being able to sleep. Not considering this social cost (both positive and negative) will lead to the production of an amount of the good that is greater or less than what is socially desired, resulting in a non-efficient allocation of resources. This could be resolved if the parties involved negotiated (and, therefore, the externalities "become internalized"), but even if it were possible to locate all the potential beneficiaries or injured parties, it would be difficult to reach agreements, and, moreover, were agreements to be reached, the transaction costs could exceed the benefits generated by the elimination of undesired external effects.

Nowadays, so-called network externalities associated with the growth in the number of users who use a service are gaining importance. There are direct and indirect network externalities. The first arise from the fact that each new

subscriber benefits from access to the group of preexisting users, but at the same time assumes a new possibility for communication (real or potential) for this customer base already connected. The second arise from an increase in the quality or quantity of available services, a catalogue that grows with the number of users.

Market Situation

Failure of Competition

The prevailing opinion in economics is that perfect competition is the market structure that leads to efficient outcomes. The problem is that markets with perfect competition are a fiction, since the conditions required to receive this description are impossible to achieve in practice. There are several types of obstacles to perfect competition: differentiated (not uniform) products, lack of information, producers of an influential size that use their power to hinder the actions of their rivals, need for prior investment or other entry barriers. Therefore, in practice almost all markets have imperfect competition. Or the other way round, it could be interpreted that a market failure would be the outcome of almost all markets.

As the catalogue of possibilities is extremely extensive and covers any situation between perfect competition and a monopoly, the problem lies in deciding when the failure of competition is considered sufficiently significant to assume that it generates non-efficiencies. Furthermore, markets are dynamic and situations change. It is in this respect important to determine what constitutes a "reasonable" waiting period before assessing whether or not obstacles to developing "sufficient" competition are disappearing.

Natural monopolies are included in this category of competition failures, even though on some occasions they are mentioned as independent market failures. It is important to stress that it is not market structure per se but the result to which this structure can lead that generates the market failure: if only one bicycle shop existed in a town with a population of 5,000 (in which "there is no space" for two shops), this would not be a problem; the problem would be that its owner would

take advantage of his condition as the only supplier to set abusive prices or conditions.

Incomplete Markets

In this case, the problem is not that market structure is far from perfect competition. It is simply that no one provides the service to certain users. Properly speaking (in terms of efficiency), it is only possible to talk of incomplete markets when there is a demand not met by producers, and the cost of satisfying this demand is lower than what those seeking the products would be willing to pay.

Information Failures

Strictly speaking, information failures are another of the causes that contribute to imperfect competition. The point of considering that it is an autonomous market failure comes from its special importance and from the fact that it also affects the demand side, unlike other “imperfections” linked to the offer.

If the information is incomplete or scant, the producer could not use the most suitable factors or reach all potential customers; in turn, the consumer could not choose the product or supplier that most suits him. One particular case is that of the “experience goods,” in which it is necessary to have had a prior experience before fully appreciating their value: the consumer’s lack of knowledge can reduce potential demand.

When information is asymmetric, the parties have different knowledge of a specific fact and the best informed party may use this advantage for his benefit. Asymmetries can lead to different situations of non-efficiency. Some of them have been formalized as specific categories. Adverse selection occurs when the majority of a market is made up by goods/customers/producers that the other party would not choose having all the information (insurance is taken out by those that are more likely to need it, something the company does not know; in a used items market, most present hidden defects). A moral hazard problem may exist when someone bears the potential negative consequences of a certain action performed by someone else, an action that is not observable for the first (and therefore, for instance, individuals

can assume greater risks in their decisions or even be tempted to cheat).

Other Possible Public Goods

Merit Goods

Merit goods are those whose consumption the State judges to be “positive” and, therefore, considers it appropriate to encourage it. Examples are education or using a seat belt in cars. Their opposites are demerit goods, such as the consumption of drugs. In merit (or demerit) goods, therefore, public opinion differs from the private assessment. There is an interest attributable to the community as a whole that does not result from the “mere” addition of individual interests. Whoever judge efficiency by assessing common or social interest in this way do then consider that we are facing a market failure.

It is not often, however, that merit goods appear in this category. For many authors, the foundation of the argument presented in the above paragraph has nothing to do with the ability or inability of the market to supply these goods efficiently. Others, even recognizing that we are facing cases of “consumer myopia” (in which consumers would not be able to assess self-interest; merit goods would become exceptions to the premise that it is the consumers themselves who are better placed to maximize their welfare according to their current income), place them in a different category of possible justification of public intervention. Finally, others consider that we are facing a case of mere presence of externalities.

Macroeconomic Situation

The fact that macroeconomic indicators are not performing well seems to indicate that the market (understood as an abstract entity formed by the union of all specific markets of goods and services) is not operating correctly, that is, it is not achieving an efficient outcome. Specifically, in the presence of a high unemployment rate, it would be logical to think that the economy could achieve a better (more efficient) outcome if part of the now wasted resources was used.

In order that this failure *of the* market be caused, failures *in some* markets or also in the

structures framing the development of economic activity (and which, therefore, affect all markets) should be produced. This feature is the reason why there is a view (not widely shared) that advocates for the existence of a market failure.

Equity

Income distribution criteria are usually considered an additional cause among the reasons that could justify State activity. Some authors, however, believe that in situations in which wealth distribution is very unequal, it is also necessary to talk about market failure. Their argument is that people with scant purchasing power can barely “communicate” with the market to make it aware of their needs, since only those who can pay the prices of the goods and services offered by companies manage this. Other authors consider that achieving an equitable society (or at least the reduction of poverty) would enter into an extensive definition of public good.

Market Failure: History

José Luis Gómez-Barroso
Dpto. Economía Aplicada e Historia Económica,
UNED (Universidad Nacional de Educación a
Distancia), Madrid, Spain

Abstract

The existence of market failures is linked to any opinion on the role reserved for the State in

the economy. In practice, this means that the notion of market failure (though not necessarily the term) can be traced back throughout all contributions made to economic science. This entry reviews the historical evolution of the opinion on market efficiency and, consequently, of the opinion on the existence of market failures.

Definition

Market failure is any situation in which the autonomous action of the market does not lead to an economically efficient outcome.

Introduction

The goal of this entry is to obtain some knowledge, albeit meager, of the different conceptual positions with regard to market failures. To that end, it reviews the historical evolution of the opinion on market efficiency and, consequently, of the opinion on the existence of market failures. It is obvious to say that, as in many branches of knowledge and specifically in economics, those that are considered landmarks are based to a large extent on previous developments and the mere description of the most significant contributions necessarily leaves other valuable works to one side.

Historical Evolution of Economic Thought on Market Failures

Economic literature usually awards Bator (1958) the merit of having coined (or of at least having used it for the first time in a publication) the term “market failure,” defined as *the failure of a more or less idealized system of price-market institutions to sustain “desirable” activities or to estop [sic] “undesirable” activities*.

However, the existence of market failures appears to be explicitly or implicitly linked to any opinion on the role reserved for the State in the economy. This means, in practice, that one

way or another, the notion of market failure (though not necessarily the term) can be traced back throughout all contributions made to economic science. And although the work of Adam Smith, and his “invisible hand,” would seem to mark, in the opinion of many, a starting point in the construction of a system capable of suitably assessing the question of efficiency in markets, what is true is that reasonings in one or another sense, with varying degrees of rigor, can be found in any chapter of the history of economic thought.

It can be generically stated that all schools prior to Smith had doubts about whether private activity (the markets) managed to reconcile individual and social welfare. The ancient Greek thinkers, who did not conceive of the economy as an autonomous discipline, saw in its fellow citizens’ pursuit of wealth a danger for the harmony of social order. Consequently, both Aristotle and Plato invoked strict control of economic activity by the State. In *Politics*, Aristotle proposed a superintendency whose main functions were to see that everyone involved in transactions was honest and holds to their agreements and contracts and that orderliness was maintained; some authors have even suggested that Aristotle’s idea was that these supervisors could set prices (Mayhew 1993).

With all the considerations derived from some very different context and motivation, these ideas were taken up again in the Middle Ages by scholastics to reach some similar conclusions: the sinning nature of man means that, against the will of God, his love for himself comes before his love for others and, therefore, the result of unregulated individual activity (ergo the market) does not agree with divine dictates. The intervention of the authority to ensure the harmony of socioeconomic order is, once more, the corollary of this reasoning.

For mercantilists, in the sixteenth and seventeenth centuries, it was not the precepts of justice, be it divine or not, but national interest that was discredited when self-interest was pursued. And given that the first representation of this national interest is the accumulation of precious metals, commercial activity is the sector where control of private initiative should be directed at in the first place.

As a reaction to mercantilism, in the eighteenth century, the physiocrats postulated the abolition of obstacles to trade. Even though their thinking often appears to be associated with the phrase *laissez-faire, laissez-passer*, the pursuit of self-interest, derived from an excessive demand for manufactured and luxury goods, continued to be part of the problem that had to be resolved (Medema 2009). In fact, François Quesnay, one of the greatest representatives of this school, advocated control of the markets, especially of agrarian markets, given their special transcendence due to agriculture being the source of the *produit net*.

What distinguishes Adam Smith from his predecessors is the assessment of the result that the sum of individual actions produces: even if individuals do not consider in their actions anything similar to the common good, but rather the strictly personal, the most beneficial outcome for society is derived from the sum of all these actions. It is important to stress the idea of “sum,” since Smith in *Wealth of Nations* gives some 60 examples in which the pursuit of self-interest causes harmful consequences for social good (Kennedy 2009). Moreover, the idea of an invisible hand infallibly guiding the markets is more a modern interpretation of his thinking than the foundation of his work, in which he only uses the expression incidentally and in the religious and cultural context of his time (among many others Harrison 2011; Kennedy 2009). Whatever interpretation is given to the metaphor of the invisible hand, what Smith is clear about is that public interference could not improve the result of private activity. Again, here it is possible to make a (important) qualification, since the three functions assigned to the sovereign in the system of “natural freedom” described in Book IV of *Wealth of Nations* are defense, justice, and “the duty of erecting and maintaining certain public works and certain public institutions, which it can never be for the interest of any individual, or small number of individuals, to erect and maintain,” an exception that has even led to calling him “cautious interventionist” (Reisman 1998).

In spite of all the detailed statements that can be made on what Smith wrote, it is at least

unambiguous that the market should be much less guided by governments or religions in his system of natural freedom than in all contributions that had been made up to then. His vision was shared, and refined, by the classical economists of the nineteenth century. Without being too ardent in their defense of *laissez-faire*, as they are often represented, for them the pursuit of self-interest, duly channeled through the activity of the markets, produces results that, on most occasions, are better than any other that could be obtained by government policy. The assessment of those results and, therefore, the conclusion they reach incorporate ideas developed by Jeremy Bentham and his utilitarianism ethic.

By the middle of the century, some nuances on firmly held concepts began to be introduced. The first to do so was John Stuart Mill, who in his “harm principle” puts as a limit to individual activity the cases in which said activity negatively affected the interests of others, which in modern terminology would be called the presence of negative externalities. As with so many theorists, his thinking is more complex than what is often presented: the circumstances in which public intervention could be admissible include situations in which individuals are not able to judge the result of their own actions (e.g., with regard to education). The above notwithstanding, Mill shares his reservations regarding public intervention with classical economists (there is a clear rule for not interfering, but none for interfering), though these reservations come more from his misgivings regarding the competence of governors than from some solid theoretical principles. Henry Sidgwick extended even further the catalogue of situations in which the principle of *laissez-faire* did not maximize common welfare. Examples are the overexploitation of natural resources, the occasions on which companies do not offer sufficient quantities of goods or services because they cannot recoup their investment or the cases in which there is not enough information on the effects of a certain product or action. For Sidgwick, a direct need for public intervention did not, however, come about in these situations. His answer to the question follows the rules of utilitarianism to their extreme and is, therefore,

much more pragmatic than that of Mill: the cost of potential intervention (that includes aspects that already concerned many of his predecessors, such as corruption and the possibility that certain groups are intentionally favored) should also be valued and then confronted with the potential benefit obtained.

At the dawn of a new century, economists from the Cambridge School applied the tools of marginalism to the problem of market limits. Alfred Marshall, by means of the consumer surplus calculation, identified situations in which public activity could increase welfare. Arthur Cecil Pigou, comparing social and private net marginal product, gave much more concrete form to what we today call the theory of externalities. His book *The Economics of Welfare* (Pigou 1920) became an obligatory support or criticism in any subsequent contribution to the debate. The role reserved for the State was, according to Caldari and Masini (2011) and despite what is usually argued, more important for Marshall (for whom the market should be substituted in questions of social relevance) than for Pigou (for whom it should merely be complemented). All this in theoretical terms, since in practice (normative economics against positive economics) both authors, especially Marshall, did not openly commit to intervention given the limitations and inefficiencies that both pointed out in the political processes (Backhouse and Medema 2012).

In the following decades, these misgivings disappeared to the extent that economists who extended the work of Pigou not only kept enhancing and shaping the theory of externalities but made progress in the mathematical demonstration of the benefit generated by public intervention (therefore necessary) in these situations (Meade 1952; Scitovsky 1954; Buchanan and Stubblebine 1962). Also, by the middle of the century, further progress in the categorization of public goods was made; the work of Samuelson (1954), where the characteristics of “collective consumption” goods are described, and that of Buchanan (1965), on impure public goods, merit to be highlighted.

But at the same time as this current was developing, other economists were challenging their

conclusions: the critical work of Coase marks an inflection point accompanied in time by the theory of Government failures.

Though sketched in other previous works, it was in *The Problem of Social Cost* (Coase 1960) that Ronald Coase structured his arguments. For him, when an activity is restricted due to the presence of negative externalities, there is also a cost associated with the restriction of such activity that is not taken into account in the calculations of social and private welfare. Which of the two “damages” is permitted is a question of assigning property rights. That assignation, though, does not necessarily lead to an efficient outcome. Ideally, it is not public intervention, but rather negotiation (the market) that could lead to an optimal (efficient) situation if the rights were well defined and there were no transaction costs. When this is not fulfilled, other options are possible. Regulation is one of them. However, if the costs associated with regulation exceed those it aims to prevent, it would leave not doing anything as the only solution; thus, the importance of having an appropriate institutional structure.

It was also in the second half of the century that a theory that did not strictly refer to market failures, but which should compulsorily be mentioned, was formulated: it is the parallel theory of Government failures. The precedents of the school of public or collective choice, as they are known, can be traced in the work of the Italian school of *scienza delle finanze* and of Knut Wicksell, who had incorporated public decision processes into theoretical analyses, thereby turning them into a factor that also determines what should be the nature and extension of the functions of the State (see Medema 2009), and further on in the work of Kenneth Arrow (most especially in Arrow 1951). With this foundation, some economists from the universities of Virginia and Chicago in the early 1960s developed a theory whose maxim was that individuals who choose between alternatives are guided by an actual rationality, both when they do so in the public function as when they choose it for themselves: they always tend to maximize self-interest.

Further on in the second half of the twentieth century, some developments came about in the

theory of market failures, very linked overall to the exploration of the consequences of the asymmetries of information, which includes concepts such as adverse selection (the famous market for “lemons” described in Akerlof 1970), the moral hazard, or the lock-in effects. There has also been abundant literature theoretically or empirically resisting these advances: a dozen studies are compiled in Cowen and Crampton (2002).

At this point, it is apparent that some important schools have been left out of this historical summary. Though they have not directly referred to market failures or even to self-interest, their concept of the role of the State enables us to infer what their position is in this regard. Here we consider three that are basic for understanding modern economic thought: Marxism, the Austrian School, and Keynesianism.

For Marxism, the market always generates undesired results and, therefore, does not consider perfect markets (in which there is also capitalist exploitation and economic crises) as a desirable or reasonable end. Therefore, market failures are an irrelevant argument or, from another perspective, all markets are pure failure.

The spontaneous order advocated by the Austrian School generates a more efficient allocation of society’s resources than that which any design can achieve. There are, therefore, no market failures, or rather it would be impossible to know whether the market is failing. To do so it would be necessary to carry out an impossible assessment, since they deny the neoclassical concept of efficiency that is substituted by the non-hindrance of the actions of individuals. In this respect, any market failures would come from public action.

Finally, Keynesianism places the emphasis on the stickiness of prices and (especially) of wages in the short run, a circumstance that makes markets with no intervention generally not able to generate efficient outcomes.

Mass Tort Litigation: Asbestos

Michelle J. White
University of California, San Diego, La Jolla,
California, USA

Abstract

Litigation over harm due to asbestos exposure is the largest mass tort in U.S. history. This article explores why the asbestos mass tort grew so large and argues that a large set of factors, rather than a single cause, are needed to explain the size of the asbestos mass tort. Among these factors are the seriousness of asbestos diseases and the fact that harm due to asbestos exposure was concealed by producers of asbestos products, changes in the law and legal procedures that favored plaintiffs, the large number of both potential plaintiffs and potential defendants, and plaintiffs' lawyers high profit from finding and representing asbestos claimants. I also argue that because of the unique circumstances explaining asbestos litigation, future mass torts are unlikely to be as large. The article also discusses research on asbestos litigation and explores various approaches—successful and unsuccessful—that have been proposed to reduce the number of asbestos claims.

Definition

Mass Tort: A mass tort involves numerous plaintiffs filing civil lawsuits against one or a few

corporate defendants in state or federal court. The plaintiffs allege that they were harmed by exposure to products produced by the defendants. Lawsuits may or may not be grouped in a class action. Law firms representing plaintiffs in mass torts often use advertising to locate and recruit plaintiffs.

Asbestos litigation is the largest mass tort in US history. As of 2002, 730,000 people had filed lawsuits against more than 8,400 defendants, and the cost of resolving claims was estimated at \$70 billion. The number of claims increased fourfold in the 1990s, and, in 2000 alone, 12 large companies reported that 520,000 new claims were filed against them. Because individual plaintiffs typically sue many defendants, estimates of the total number of asbestos claims range as high as 10 million. As of 2003, 73 corporations had gone bankrupt due to asbestos liabilities (Carroll et al. 2005). Asbestos litigation has been extremely profitable for lawyers, since 57% of spending goes to lawyers' fees (Carroll et al. 2003). Two studies in 2001 predicted that asbestos litigation in the USA would eventually cost \$200 billion (Angelina and Biggs 2001; Bhagavatula et al. 2001).

Asbestos was once considered to be a "miracle mineral" for its effectiveness as insulation and in preventing the spread of fires. It was used in ships, buildings, and consumer products, including wall-board, roofing, flooring, pipes, automotive brakes, hair dryers, children's toys, clothing, paper, and gardening products. Asbestos was used to coat the steel girders of skyscrapers such as the World Trade Center in New York, to insulate furnaces, and to make theater curtains fire resistant so that backstage fires would not spread to the seating area. Because asbestos had so many uses, estimates of the number of people who were exposed to it range from 27 to 100 million (Biggs et al. 2001).

But asbestos crumbles into microscopic fibers that become airborne and embed themselves in the lungs, causing a variety of diseases. Mesothelioma is cancer of the pleural lining around the chest and abdomen and is quickly fatal. Asbestosis is scarring of the lungs that reduces breathing capacity; it can range from non-disabling to fatal.

These two are "signature diseases" that are uniquely associated with asbestos exposure. Other asbestos diseases include lung cancer, gastrointestinal cancer, and pleural plaque, which is non-disabling thickening of the pleural lining. These latter conditions can be caused either by asbestos exposure or by other factors, such as smoking. Most asbestos diseases have a long latency period, so that they do not develop until 20–40 years after exposure. Individuals' likelihood of developing asbestos disease is low, but increases as the length and intensity of exposure rise (Carroll et al. 2003).

Asbestos exposure was recognized to be harmful as early as the 1920s and safe substitutes for many of its uses were developed in the 1930s. But it nonetheless became widely used – US consumption of asbestos grew from 100,000 metric tons in 1932 to 750,000 in 1994 (Castleman 1996, p. 788). Since then, asbestos use has fallen nearly to zero, but new cases of asbestos disease continue to occur because of the long latency period.

One question concerning asbestos is why government regulation did not prevent it from becoming so widely used. The British government began in the early 1930s to regulate workplace safety in the asbestos industry and provide workers' compensation to those disabled by asbestos exposure. In the USA, many states set up workers' compensation programs around the same time. However workers' compensation programs were oriented toward providing compensation for immediate workplace injuries, while asbestos exposure caused diseases that developed many years later and were not initially connected with asbestos exposure. Because statutes of limitation were short, most workers no longer qualified for compensation at the time they developed asbestos disease.

Workers' compensation systems also protected asbestos producers from liability for harm to their workers, since these systems were workers' exclusive remedy against their employers for workplace-related harm. Thus injured asbestos workers did not qualify for workers' compensation and also were barred from suing their employers for damage. And because employers were not liable for asbestos-related harm to their

workers, they had little incentive to improve workplace safety.

Workplace and product safety regulation also failed to protect workers who were exposed to asbestos. Occupational safety programs started in many US states in the 1950s and 1960s, but rules were often voluntary and poorly enforced. Some regulations actually increased workers' exposure to asbestos, such as building code regulations that required ventilation systems to be lined with asbestos insulation. As the insulation aged, it crumbled into microscopic fibers and fans blew the fibers through the workplace, where workers breathed them. Federal regulatory agencies such as the Occupational Health and Safety Administration (OSHA) and the Consumer Product Safety Commission (CPSC) came along in the 1970s and began to regulate asbestos exposure. But for many years, OSHA's workplace standards for preventing asbestos exposure were not tight enough to prevent workers from developing asbestos disease. Similarly, the CPSC's standards for limiting asbestos in consumer products in the 1970s and 1980s were mainly voluntary. Overall, state and Federal efforts to limit exposure to asbestos in the USA largely failed until the 1990s. This failure of regulation meant that many asbestos workers and product users suffered injuries due to asbestos exposure. This failure of regulation was not unique: other countries were no more successful in preventing asbestos exposure and they were generally slower than the USA to remove asbestos products from the market (White 2004; Wikipedia 2014).

In the next sections, I consider various factors that explain why asbestos litigation in the USA grew so large. I also review research on asbestos litigation and discuss various solutions – successful and unsuccessful – that have been proposed to resolve asbestos litigation.

Why Asbestos Litigation Grew

A combination of factors, rather than a single factor, was responsible for the growth of asbestos litigation. Because workers' compensation systems are workers' exclusive legal remedy against

their employers for on-the-job injuries, asbestos producers in the USA were not liable when their workers developed asbestos-related diseases. But asbestos producers were not shielded from liability to users of their products, and asbestos litigation therefore developed based on product liability law. The first successful trial of a lawsuit for damage due to asbestos exposure occurred in 1973 and involved an insulation worker who sued one of the large manufacturers of asbestos insulation (*Borel v. Fibreboard*, 443 F.2nd 1076 [5th Cir. 1973]). During the ensuing decade, 25,000 additional lawsuits were filed against asbestos product manufacturers and the number of lawsuits continued to grow. Because asbestos lawsuits were brought under products liability law rather than workers' compensation, plaintiffs could receive both compensatory and punitive damage awards. Damage awards could be in the millions of dollars, especially when juries awarded punitive damages (Berenson 2003).

One factor that favored asbestos plaintiffs was a change in products liability law in the 1960s that made producers strictly liable for harm to users of their products; previously, they were liable only if they were found to be negligent. The strict liability doctrine made producers liable as long as their products were “unreasonably dangerous,” or users were not adequately warned of the danger. The change from negligence to strict liability made it easier for plaintiffs to win asbestos lawsuits, both because asbestos products were extremely dangerous and because they rarely contained warnings.

Another factor that favored plaintiffs in asbestos litigation is that a number of plaintiffs' law firms specialized in handling asbestos claims. These law firms invested in developing evidence against asbestos producers that could be used in all of their lawsuits. The need for law firms to invest in developing evidence kept the number of entrants small, so that the asbestos litigation “industry” remained concentrated, with the ten top law firms representing 50–75% of asbestos claims filed. The high concentration meant that profits were high (Carroll et al. 2003).

In developing a strong legal case against asbestos manufacturers, plaintiffs' lawyers were aided

by the fact that several independent epidemiological studies were published in the 1960s that demonstrated strong links between asbestos exposure and asbestos disease. Asbestos plaintiffs' lawyers also developed evidence that producers conducted research on the health effects of asbestos exposure starting in the 1930s and found that exposure was harmful. But producers kept the results secret and did not warn workers or product users of the danger. This evidence of a cover-up of the dangers of asbestos exposure strengthened plaintiffs' claims in subsequent asbestos trials (Carroll et al. 2003).

The evidence suggesting a cover-up of the dangers of asbestos caused juries to frequently award punitive damages as well as compensatory damages in trials involving asbestos claims. One-sixth of all damage awards in asbestos lawsuits include punitive damages – a high proportion compared to other types of litigation. Unlike compensatory damages, punitive damage awards are often not covered by defendants' products liability insurance. The high damage awards and lack of insurance coverage made defendants eager to settle rather than litigate asbestos claims. But when claims frequently settle, they are very profitable for plaintiffs' lawyers to file, since lawyers' costs occur mainly at trial. This meant that plaintiffs' lawyers had an incentive to locate and file as many claims as possible.

Asbestos plaintiffs also benefit from the fact that they can sue many defendants. Typical asbestos plaintiffs sue 25 or more defendants, including producers of all of the asbestos products that they might have been exposed to while working or engaging in other activities. In a number of states, joint and several liability applies, so that each defendant found liable for damages is liable for the full amount of the damage award. Joint and several liability makes damage awards more valuable, since plaintiffs can collect up to the full amount of the award from any defendant(s) or their insurers. Thus even if some defendants pay little or nothing, damage awards can be collected from other defendants.

Another advantage that plaintiffs have in asbestos litigation is that their lawyers choose the most favorable court in which to file

lawsuits – a phenomenon known as “forum-shopping.” Plaintiffs' lawyers handling asbestos claims have a choice between filing in Federal versus state courts, and, if the latter, they can choose a state that has pro-plaintiff laws and legal procedures. Particular states are often favored because they do not require judges to approve lawyers' fees when claims are settled (this means legal fees can be higher), because they use joint and several liability and/or because they do not limit the size of punitive damage awards.

Within a particular state, plaintiffs' lawyers also choose a favorable location in which to file claims. Many asbestos claims are filed in out-of-the-way county courts where plaintiffs' lawyers have a relationship with local judges. These judges can help plaintiffs' lawyers by reducing defendants' ability to conduct pretrial discovery, scheduling trials at short notice so that defendants' lawyers have difficulty getting to the court in time, directing juries to consider awarding punitive damages, and pressuring defendants to settle. In return, plaintiffs' lawyers contribute to judges' reelection campaigns and benefit the local region by bringing in economic activity that raises demand for local hotels and restaurants. Favored locations for asbestos litigation in the past have included Madison, Illinois, Kanawha, West Virginia, and Jefferson County, Mississippi, as well as larger cities such as Philadelphia, Houston, and San Francisco – the latter because they are home to large shipyards and many former sailors who were exposed to asbestos while serving on navy ships.

Judges also developed new legal doctrines and legal procedures that favored plaintiffs and therefore encouraged plaintiffs' lawyers to file claims. One important change was a decision that greatly increased insurers' liability to asbestos claimants by legally reclassifying products liability insurance policies as premises insurance policies. While products' liability policies have a coverage limit that limits insurers' total liability under the policy to a fixed dollar figure, premises policies apply the coverage limit to each occurrence – where each individual asbestos claim is interpreted as an occurrence. Other legal changes

expanded insurers' liability for claims made after the time period when their policies were in effect. These changes greatly increased insurers' liability for asbestos damage by reviving old insurance policies that had already paid out their coverage limits (Epstein 1984; Anderson 1987).

Another legal change was that judges allowed multiple asbestos lawsuits to be litigated together, thus creating informal class actions. Asbestos plaintiffs' lawyers initially tried to have all asbestos claims certified as a class action in Federal court and settled all at once, but the Supreme Court overruled two settlements of class actions involving asbestos claims (*Amchen Products v. Windsor*, 117 S.Ct. 2231 (1997) and *Ortiz v. Fibreboard Corp.*, 119 S.Ct. 2295 (1999)). After these two decisions, plaintiffs' lawyers shifted to filing most asbestos claims in state courts. Judges in these courts allowed groups of lawsuits to be consolidated for either the pretrial or the trial stages of litigation, or both, using a procedure known as mass joinder. These consolidations often combined multiple claims by out-of-state plaintiffs with a small number of claims by in-state plaintiffs. The total number of claims consolidated ranged from a few to up to 9,600. Judges would hold a single trial before a single jury for all claims, with the jury sometimes making separate decisions for each plaintiff and sometimes making a single decision for all plaintiffs (Carroll et al. 2005). Combining multiple lawsuits for litigation benefits plaintiffs by making the trial outcomes more positively correlated. This makes going to trial more risky for defendants, because losing many cases at once could exhaust their insurance coverage and force them to file for bankruptcy. The more claims that are combined, the more bargaining power plaintiffs' lawyers have. Thus when large numbers of asbestos claims are consolidated for trial, defendants are likely to settle even claims that are legally weak.

Another legal change that benefitted plaintiffs in asbestos lawsuits is the use of bifurcated or reverse bifurcated trials. In a bifurcated trial, evidence concerning liability is presented first and the jury decides separately on each defendant's liability. Then the trial is suspended while

plaintiffs and defendants who have been found liable bargain over a settlement. If they fail to settle, the trial is resumed at a later date – sometimes with the same jury – for the damages portion of the trial. In a reverse bifurcated trial, the format is the same, but damages are tried in the first stage and liability in the second stage. Bifurcation saves on trial time relative to holding a unitary trial if the parties settle after the first stage. The parties are also more likely to settle at the end of the first stage than before the trial starts, since they have some of the information that the trial will generate.

Reverse bifurcation was developed specifically for asbestos trials and is particularly thought to benefit plaintiffs. This is because plaintiffs often have severe damage from their asbestos exposure – making damage awards high. In contrast, plaintiffs' claims are often weak on the liability side, because they cannot show that they were exposed to particular defendants' asbestos products. So using reverse rather than straight bifurcation strengthens plaintiffs' bargaining power in settlement negotiations, because the information generated by the first stage of the trial is very favorable to plaintiffs and raises their bargaining power in settlement negotiations.

Bouquet trials are another procedural innovation developed for asbestos litigation. In a bouquet trial, a small group of asbestos plaintiffs is selected for trial from a larger group of consolidated claims. The trial group includes plaintiffs with severe asbestos disease and plaintiffs with no impairment. The idea of the bouquet trial is that the outcomes at trial for the various types of plaintiffs will be used as a template for settling the remaining claims in the larger group. Using a bouquet trial allows larger numbers of claims to be consolidated, since a bouquet trial can be held even when the full consolidated group of claims is too large to hold a single trial. One well-known example is a trial of 12 asbestos claims in Mississippi that were selected from a larger group of 1,738 asbestos claims. At the bouquet trial, the jury awarded plaintiffs damage of \$4 million each. The prospect of the jury assessing similarly high damage awards for the remaining plaintiffs caused defendants to settle

all the remaining claims on very favorable terms (Parloff 2002).

Another factor that allowed the asbestos mass tort to grow so large is the large number of potential plaintiffs. As discussed above, the widespread use of asbestos meant that millions of people were exposed. Typical plaintiffs include ex-sailors who were exposed to asbestos on ships during World War II, workers who install insulation, workers in shipyards and steel mills, and textile workers who were exposed to airborne asbestos fibers in factories. Plaintiffs' lawyers search for new plaintiffs by extensive advertising and by conducting mass screenings. A frequent procedure was to bring a van equipped with an X-ray machine to a factory and take chest X-rays of all the factory workers. Any found to have scarring or thickening of the lungs or the pleural lining would be signed up as asbestos plaintiffs. Doctors often read hundreds of X-rays per day and found that nearly all of them had asbestos-related damage. More recently, plaintiffs' law firms have shifted to television advertisements to recruit plaintiffs whose exposure to asbestos may be non-work-related.

Another issue that has allowed asbestos litigation to become so large is that claims are valuable even when plaintiffs have no impairment from their asbestos exposure or had no asbestos exposure so that their claims are downright fraudulent. Because asbestos lawsuits are mainly settled rather than tried, non-impaired and fraudulent claims are valuable because they increase the size of consolidations and raise plaintiffs' lawyers bargaining power with defendants. Settlements cover both fraudulent and valid claims. Estimates suggest that as few as 10% of plaintiffs with asbestos claims have asbestos-related cancers – a widely used measure of disabling asbestos disease (Carroll et al. 2003). Legal standards that allowed non-impaired plaintiffs to collect damages are an important feature of asbestos litigation.

The asbestos mass tort also involves many types of defendants. In the first stage of the litigation, defendants were the major producers of asbestos insulation. These companies eventually went bankrupt. In the second stage, these defendants were replaced by producers of asbestos-

containing products, retailers that sold these products, and firms that operated workplaces containing asbestos. Examples include the automobile companies, sued because car brakes contained asbestos; Sears Roebuck, sued because its stores sold asbestos-containing products; 3M Corporation, sued because it made dust masks that didn't protect users from asbestos exposure if they used the masks improperly; and Crown Cork and Seal, sued because it briefly owned a company that included a division which produced asbestos-containing insulation. Crown Cork quickly sold the division that produced insulation, but nonetheless it eventually paid out \$700 million in asbestos settlements and damage awards. Both small and large firms were sued, since even small defendants have insurance. Each time new defendants were added to the litigation, previous plaintiffs filed new claims against them. Because there were so many plaintiffs and so many potential defendants, the asbestos mass tort continued to grow.

Finally, bankruptcy also played a role in encouraging asbestos litigation. Many of the large firms that produced asbestos insulation and asbestos-containing products went bankrupt due to their asbestos liabilities – the first was the Johns-Manville Corporation in 1982. When asbestos-producing firms go bankrupt, present and future damage claims against them are assigned to a trust which receives some or all of the reorganized firms' equity and uses the funds to pay compensation to asbestos victims. Congress adopted legislation defining these trusts in 1994 and required that they follow the general outlines of the Manville Trust that was set up following the Johns-Manville bankruptcy. Trusts first estimate the number and severity of future asbestos claims against them and then determine what level of compensation payments they can pay such that their funds will cover both present and future claims. Trusts payments vary with the severity of the claimant's asbestos disease and the length of exposure to asbestos. The trusts do not require that claimants show impairment from their asbestos exposure and they use quite loose standards for demonstrating exposure to the bankrupt firm's asbestos products. This was done in order to

reduce transactions costs and increase the fraction of damage payments that went to claimants rather than lawyers. However the loose standards for receiving compensation caused the number of claims to increase, causing many of the trusts to cut their compensation payments. On average, claimants with no asbestos-related impairment receive a total of around \$8,000 in compensation from all of the trusts, while claimants with moderate impairment receive around \$19,000. Compensation trusts have paid out a total of around \$17 billion to asbestos claimants (Scarcella et al. 2013).

The bankruptcy trusts encourage asbestos litigation in two ways. First, when corporations go bankrupt, their damage payments fall drastically. This encourages plaintiffs' lawyers to find new asbestos defendants to substitute for those that have gone bankrupt. The bankruptcies thus have contributed to bringing in many new corporations as defendants whose involvement with asbestos is increasingly remote. Second, although the trusts' compensation payments are relatively small, representing trust claimants is nonetheless profitable for plaintiffs' lawyers if they represent large numbers of claims. The trusts therefore encourage plaintiffs' lawyers to continue recruiting large numbers of non-impaired claimants, since the loose compensation rules allow these claimants to receive payments from many or all of the trusts.

Overall, a combination of factors is needed to explain why asbestos litigation grew so large.

Research on Asbestos Litigation

In White (2006), I examined why judges adopt the procedural innovations used in asbestos trials and the effect of both forum-shopping and procedural innovations on trial outcomes. The procedural innovations, discussed above, are consolidation of multiple lawsuits for trial, bifurcation and reverse bifurcation, and bouquet trials.

Why do judges adopt these innovations for asbestos trials? Judges in favored jurisdictions for asbestos litigation have crowded dockets. Because it would be impossible to hold individual trials for all cases, judges favor procedures that

encourage the parties to settle and therefore reduce trial time. Consolidating claims for trial is a method of reducing trial time, because only one jury must be selected and some of the evidence can be presented only once for all plaintiffs. Consolidation also increases the probability of settlement, because trial outcomes become more positively correlated and defendants therefore find it riskier to go to trial. Bifurcating trials reduces trial time relative to holding a unitary trial, because the information generated in the first phase of trial increases the probability of settlement when the parties bargain after the first phase. Finally, bouquet trials save trial time by allowing larger numbers of asbestos claims to be consolidated – if a trial is needed, then a bouquet trial can be held when the number of claims in the consolidation would otherwise make it too large for a single trial.

The study uses a dataset consisting of all asbestos lawsuits that were tried in court to a verdict on liability or damages or both between 1987 and 2003. Each observation consists of a trial of a single plaintiff's asbestos claim against all defendants. There were around 5,200 observations in the dataset, implying that less than 1% of asbestos plaintiffs' claims go to trials.

The data include the plaintiffs' alleged disease, the trial venue, the trial outcome, whether the claim was consolidated for trial and the number of claims in the consolidated group, whether the trial was bifurcated or reverse bifurcated, whether a bouquet trial was used, and the number of defendants that each plaintiff sued.

Half of all claims had individual trials, while the rest were consolidated with at least one other claim for trial. Approximately one-fifth of trials were bifurcated or reverse bifurcated and 4% were bouquet trials. Use of the procedural innovations was geographically concentrated: bifurcated trials were frequently used in Manhattan and Philadelphia, while bouquet trials mainly occurred in Mississippi. Sixty-four percent of plaintiffs were awarded compensatory damages and the average compensatory damage award (contingent on defendants being found liable) was \$1.3 million in 2003 dollars; 20% of plaintiffs were awarded punitive damages and the average punitive

damage award (contingent on defendants being found liable for both compensatory and punitive damages) was \$1.8 million. Plaintiffs' expected return from going to trial was \$1.1 million for the entire sample, with those having mesothelioma receiving around \$3 million more.

To examine the effect of consolidating claims for trial on the correlation of the trial outcomes, I computed a correlation coefficient for all trials involving two plaintiffs and compared the result with the correlation coefficient for single-plaintiff trials when plaintiffs were randomly assigned in pairs. I also followed the same procedure for three- and five-claim consolidations. The results show that the correlation coefficient of expected total damages ranges from 0.84 to 0.92 in the actual groups, compared to only 0.01–0.04 in the randomly assigned groups. The results were similar if only liability or only damages are considered. These results suggest that consolidating claims for trial makes trial outcomes much more positively correlated and supports the hypothesis that going to trial in a consolidation is much more risky for defendants.

To examine the effect of forum-shopping and the procedural innovations on trial outcomes, I estimated probit regressions explaining whether plaintiffs were awarded compensatory damages and whether they were awarded punitive damages conditional on receiving compensatory damages. I also estimated Tobit regressions explaining the amount of compensatory and punitive damages, with damages set equal to zero when the plaintiff loses. Forum-shopping was found to be extremely favorable to plaintiffs, with plaintiffs' probability of receiving compensatory damages increasing by up to 30 percentage points in the most favorable jurisdictions relative to the most commonly used jurisdiction. Also plaintiffs' probability of being awarded punitive damages rose by up to 91 percentage points in the most favorable jurisdiction relative to the most commonly used jurisdiction.

Use of the procedural innovations also increased plaintiffs' expected return from going to trial. Having a bifurcated trial raised plaintiffs' probability of being awarded compensatory damages by 27 percentage points and raised compensatory damage awards by \$924,000. Having

a bifurcated trial also increased plaintiffs' expected return from going to trial by \$650,000. But bifurcated trials did not significantly increase plaintiffs' probability of winning punitive damages or the size of the punitive damage award. Having a bouquet trial raised plaintiffs' probability of being awarded punitive damages and caused both compensatory and punitive damage awards to be higher. Plaintiffs' expected return from going to trial increased by \$1.2 million when a bouquet trial was held. Having a small consolidated trial consisting of 2–5 plaintiffs' claims increased plaintiffs' probability of winning both compensatory and punitive damages, but was associated with lower compensatory damage awards. Surprisingly, having a larger consolidated trial of six or more plaintiffs did not significantly change plaintiffs' returns from going to trial.

Overall the results suggest that the return to plaintiffs and their lawyers from filing asbestos claims is greatly increased by forum-shopping and by plaintiffs' lawyers picking jurisdictions where judges use the procedural innovations. Although the research did not address the issue of how forum-shopping and procedural innovations affect the size of asbestos settlements, the standard economic model of settlements suggests that they mirror trial outcomes and are higher in courts where plaintiffs' expected returns from going to trial are higher (Mnookin and Kornhauser 1979). Thus forum-shopping and procedural innovations are also likely to raise the amount that defendants pay to settle asbestos claims.

Methods of Resolving Asbestos Litigation: Hypothetical and Actual

In this section, I consider solutions for resolving asbestos litigation – including both proposed solutions that were never adopted and actual solutions that were.

One proposed solution in the 1990s was to certify a class action of all asbestos claimants. In a class action, all asbestos claims are combined in a single lawsuit and all are resolved at once, usually by a settlement. Both present and future

asbestos claims are resolved. Individual plaintiffs would be bound by the outcome of the class action and would not have had the right to opt out. The Federal courts certified two class actions of asbestos claimants, but – as discussed above – the US Supreme Court rejected both class certifications in 1997 and 1999, on the grounds that asbestos claimants were too diverse to be combined into a single class.

This was followed by another proposed solution for asbestos litigation: a Federal government-administered compensation scheme for asbestos victims. The proposed bill was the Fairness Asbestos Injury Resolution or “FAIR” Act of 2005, S. 852. It was based on previous federally administered programs, one that compensated miners who developed black lung disease and one that compensated children harmed by childhood vaccines. Compensation of up to \$140 billion would have been financed by levies on asbestos producers and insurers. Asbestos victims would lose their right to file lawsuits, but would instead receive compensation from the trust. Claimants who had mesothelioma or cancer would receive the highest awards of \$1.1 million and those with less disabling diseases would receive \$25,000 or more. Non-impaired claimants would receive medical monitoring, but no compensation (Stengel 2006). However the FAIR Act was not enacted (Barnes 2011).

While both the class action settlement and the compensation scheme for asbestos claims failed, courts began in the early 2000s to adopt new procedural innovations that reduced the amount of asbestos litigation. One such device was the “inactive docket” which put claims by non-impaired asbestos plaintiffs on an inactive basis, preserving their right to sue in the future, but preventing their claims from proceeding in the legal system until they become impaired from their asbestos exposure. Inactive dockets solve the problem that plaintiffs must file claims quickly after discovering their asbestos-related harm in order to satisfy statutes of limitations. But because most asbestos claims are classified as inactive, asbestos litigation now consists mainly of plaintiffs who have severe asbestos-related diseases.

As a result of the use of inactive dockets, plaintiffs’ lawyers can no longer litigate large groups of claims consisting mainly of non-impaired plaintiffs, and they therefore have less bargaining power to force defendants to settle. The fraction of asbestos damage awards going to non-impaired plaintiffs has fallen from around 50% in 1997–1999 to less than 5% in 2013 (Scarcella et al. 2013). This change has greatly reduced plaintiffs’ lawyers’ return from recruiting non-impaired asbestos claimants. It has been so successful in reducing the volume of asbestos litigation that an observer is led to wonder why judges did not adopt it much earlier.

Another recent development is that some states that were centers for asbestos litigation have adopted legal reforms to discourage the filing of asbestos claims in the state. An important change in several states was to bar judges from consolidating out-of-state with in-state asbestos claims for litigation. As a result, out-of-state claims could no longer be litigated in the state and therefore plaintiffs’ lawyers could no longer put together large consolidations. Among states that previously allowed large consolidations of asbestos claims, West Virginia, Mississippi, and Illinois all made changes along these lines in the early 2000s. Several other states changed their legal rules to explicitly disallow large consolidations of asbestos claims, although they generally still allow out-of-state claims to be consolidated with in-state asbestos claims. Another change is that New York, Texas, and several other states substituted proportional liability for joint and several liability to asbestos claimants, so that individual defendants are no longer liable for plaintiffs’ entire damage award. This shields non-bankrupt defendants from being held liable for bankrupt defendants’ share of plaintiffs’ damage (Hanlon and Geise 2007). The result of these changes in state law is that most asbestos litigation now involves a much smaller number of claims by plaintiffs with serious asbestos-related diseases and these claims are litigated individually or in small groups.

Finally, judges have become more likely to dismiss fraudulent claims, rather than pressure defendants to settle them. This approach was used recently to resolve a different mass tort:

claims for damage due to silica exposure. Silica litigation was a spinoff from asbestos litigation and took a similar form. Plaintiffs allege harm from inhaling airborne silica crystals that can lead to scarring of the lung lining, silicosis, or lung cancer. Because of the similarity between asbestos disease and silica disease, plaintiffs' lawyers recruit silica claimants using the same mass screenings with chest X-rays that they use to recruit asbestos claimants. In fact, plaintiffs' lawyers often file both silica claims and asbestos claims on behalf of the same individuals, using the same chest X-rays; this is despite the fact that it is rare for individuals to have been exposed to both silica and asbestos. However the judge who presided over the silica litigation dismissed nearly all of the claims on the grounds that they were fraudulent and threatened to bring criminal charges against the doctors who read the plaintiffs' X-rays. This effectively ended the silica mass tort, leaving only a small number of lawsuits by plaintiffs with severe silica-related disease. The publicity given to the silica litigation has probably made judges more likely to dismiss asbestos claims as well (Behrens and Goldberg 2005/2006).

Future Directions

Because asbestos litigation has been so lucrative, plaintiffs' lawyers have searched widely for other defective products that could serve as the basis for new mass torts, using the techniques they developed for asbestos litigation. Among potential future mass torts are litigation involving harm due to exposure to lead paint, harm due to guns, and claims of obesity due to consumption of fast food (White 2004). However none of these spinoff mass torts have been successful in court.

But the asbestos mass tort itself continues to mutate into new forms that keep it alive. One recent development is lawsuits filed by family members of asbestos workers who claim second-hand exposure to asbestos from relatives' clothing. Family members, unlike workers themselves, are not barred by workers' compensation from suing their relatives' employers. Thus they can

both sue their relatives' employers and the producers of asbestos products that their relatives were exposed to. Another new development in asbestos litigation is claims by lung cancer victims against asbestos producers and the asbestos bankruptcy trusts. Most lung cancer is caused by smoking, but plaintiffs with lung cancer nonetheless claim that their cancer was caused by exposure to asbestos. These claims qualify for compensation from the asbestos bankruptcy trusts, and, because lung cancer is a serious disease, their lawsuits against non-bankrupt defendants are not placed on the inactive docket (Nocera 2013). And since there are 200,000 new lung cancer cases each year compared to only 2–3,000 new mesothelioma cases, lung cancer claims present a valuable opportunity for lawyers to continue the asbestos mass tort.

Measure of Environmental Regulation

Vittoria Colombo
Università degli Studi di Torino, Turin, Italy

Definition

Environmental law and economics has been largely focused on the effect that different environmental rules can have on economic outcomes, while only few detected the difficulty of analysis of such subject, mainly due to the measurement of environmental stringency. There is no homogeneous way to measure environmental regulation, due to its peculiarities; environmental rules are often designed based on elements other than just the legal principle, such as geographical characteristics, scientific data, the level of pollution and the industry sector involved, and elements that must be taken into account in order of not incurring in methodological mistakes. This essay examines the main approaches and indicators of environmental regulation, considering the advantages and disadvantages of any of them. It also analyzes the main risks of a wrong

methodological approach to the measurement of environmental rules.

Environmental regulation is an atypical form of regulation, which needs to be assessed in its entirety and complexity. Its design requires scientific and technical information that are pivotal for reaching its objectives. Environmental rules are difficult to assess, since decisions on how to design a rule do not only depend on legal elements but also on scientific data, risk assessment, and scientific criteria.

Environmental Stringency

Currently the most used method of measuring environmental regulation is by looking at costs imposed by it, namely, at the *environmental stringency*, which in its broad and shared definition is the “cost of polluting by firms across different sectors and policy instruments,” where “a higher value represents a more stringent policy.” The use of environmental stringency allows to ascertain environmental regulation as a whole, and at the same time, it is sufficiently general to allow scholars to use different methods and datasets. The main conceptual difficulties in analyzing environmental stringency can be summarized in seven broad problems: multidimensionality, simultaneity and identification, trade-off between *de jure* and *de facto* situations, industrial composition, sampling, grandfathering, and lack of data (Brunel and Levinson 2013).

Multidimensionality

Environmental regulation is typically *multi-dimensional* (Wing-Hung et al. 2011): it deals with different media, such as soil, water, and air, as well as different pollutants that affect those media (dioxin, chemicals, carbon dioxide, etc.). Moreover, it has different recipients: firms, consumers, households, and even public administration itself. Finally, it can set standards or limits that vary on the basis of several factors, which can change depending on the environmental quality of territory, on the technology

used by firms, or on the sector in which firms operate (Kozluk 2014a). On the one hand, there could be many environmental regulations applying to the same industry, aiming at protecting different media (water, land, human health, etc.); on the other hand, policy-makers' decisions are also relevant, with the same rules applied in different ways depending on several internal or external factors that have a link with environmental standards. The level of emissions, the location of the activity, the technology applied in a certain plant, or the sector in which the firm operates can have a decisive weight on the decision not only on the application of a certain rule but also on the intensity of the instrument itself. The intensity of the application of instruments depends on factors that are linked with the environment, and the decision to forbid a certain production method in a region could depend on specific geographical characteristics of the territory.

Multidimensionality is the reason why case studies on a specific industry sector are limited, because they are not representative of other categories not covered by that specific regulation (Sauter 2014).

De Jure and De Facto Applications

The *de jure* stringency derives from environmental legislation applied in a certain legal system *ex ante*, while the *de facto* one corresponds to the real application of the *de jure* instruments. This assessment is made by looking at courts' decisions, namely, at the difference between regulation and its enforcement. *De facto* application of the rules may also involve other informal elements that are not easily detectable as judicial decisions: enforcement of rules does not only occur in courts but can take different shades, i.e., it could consist in a fine given by the administrative local authority but also in some checks made by the public authority in the concerned sites. For some environmental regulations, soft mechanisms are used, i.e., flexibility mechanisms or the provision of consultations with the authority in charge of enforcement.

Simultaneity and Identification

Simultaneity is the difficulty of identifying the direction of causality between the rule and its effect. Countries may introduce stricter environmental regulations in order to address concerns on high-polluting industries. However, many pollution-intensive industries have consistent political power and can lobby decision-makers to enact lax environmental regulation. This makes difficult to assess the causal link between a certain environmental policy and its results (Brunel and Levinson 2013). Similar to the problem of simultaneity is the broader problem of identification, which in this case occurs when there is a problem in identifying whether a certain result is due to an environmental rule or to other regulatory instruments, i.e., legislation on employment, or to certain market characteristics (Malatu 2008).

Some scholars conducted natural experiments to avoid such problem, taking into account relevant changes in regulation forced by external factors (as a Supreme Court decision or international treaties' implementation), and comparing the *ante-* and *post-*scenarios (McConnell and Schwab 1990; Henderson 1996), others looked at instrumental variables correlated with the regulatory stringency (Xing and Kolstad 2002; Levinson and Taylor 2008) but uncorrelated with the measure of economic activity.

Industrial Composition

Industrial composition of countries may be due to endogenous sources that are not measurable, such as the geographic characteristics or natural resources in the country, i.e., carbon or natural gas. Industrial composition, if not considered, can cause methodological problems.

Sampling and Grandfathering

Sampling deals with the causal link assessment but related to the sample of industries subject to a given environmental policy. An industry's market

share in a country can be itself the result of a determined environmental policy, i.e., high-polluting industries can be present more in a country than in another, because of that country's environmental policy toward a certain industry sector. This problem has to be taken into account when assessing the effect of policy stringency in a sector.

Also grandfathering, namely, the provision according to which new rules apply only to new situations, while the old rules continue to apply to existing situations, could create problems. In the field of environmental law, stricter rules may apply to new plants or pollution sources, while lax ones are applied to old sources of pollutions that, most probably, are also the most polluting ones. This problem concerns more consumers than firms: whereas the former ones are not bound to buy new products – consumers are not obliged to buy a new car and can continue to drive the old one, which is much more polluting than new models – the latter ones are often shifting to new technologies because they are obliged by law to do so (Heutel 2010).

Lack of Data

Lack of data must not be intended in absolute terms, but as lack of data giving source to a robust outcome. This factor is linked with multi-dimensionality, identification, simultaneity, and sampling; often the available data consider just a small part of environmental legislation while not dealing with the assessment of the quality and quantity of all environmental regulation applied in a determined country or region.

Approaches in Measuring Stringency

Although the definition of environmental stringency is widely accepted, it is not the same for what it concerns its *measure*.

The main challenge of measuring environmental stringency is the delineation of a conceptual framework that considers all the principal layers of

environmental law and that includes them in the analysis (Sauter 2014). The distinction between market- and nonmarket-based instruments allows to assess the impacts that these two regulatory approaches may have. However, this distinction alone can be misleading and too reductive, because it does not consider other elements such as flexibility and stability of regimes (Johnstone et al. 2010). De Serres (De Serres et al. 2010) distinguishes four categories of market-based instruments: (a) environmental taxes, (b) pollution trading systems, (c) deposit-refund systems, and (d) subsidies for incentivizing environmental friendly activities. Nonmarket-based instruments include the general category of (a) command and control regulations, (b) technology-support policies, and (c) voluntary approaches.

The main approaches for measuring environmental regulation will be presented in the following.

The first approach looks at changes in a single regulation or rule. The second looks at perceptions that firm directors, public officials, and, more generally, people directly touched by environmental regulation have on its stringency. The third considers shadow prices for environmental inputs or expenditures related to environmental rules. The fourth looks at the variation of environmental performances to deduct a more or less stringent environmental legislation. Finally, composite measures aim at avoiding multi-dimensionality, by including all the elements in the same indicator.

Change in a Single Regulation

The advantage of looking at the effect of a change in a single regulation is the level of certainty it can bring to the analysis; the risk of multi-dimensionality is highly reduced, as well as the one of simultaneity and identification. In addition, this kind of analysis is more feasible than the general one, because of the availability of data. However, the limits are relevant. By looking at the single regulation, results will be applicable only to it and not to other sectors (Smarzynska and Wei 2001). The reason is exactly multidimensionality that, when eliminated though a circumscribed

analysis, limits the extension of the same results to other cases.

Analysis Based on Perceptions

The majority of datasets on environmental stringency are based on perceptions by businessman and firms' directors or civil servants. The advantage of such approach is the availability of data and the reliability of the analysis, which can be circumscribed by asking the same questions on a limited number of regulations or media. However, the premises are not always exempted from critics. When data are used for a cross-country analysis, perceptions are difficult to compare, since the requisites for an objective perception of situations by individuals are the knowledge of the other terms of comparison, which in such case are assumed (Becker and Henderson (2000). Interviewees should be aware of the strictness of environmental regulation in other countries in order to give an objective opinion on the one of their country. Moreover, according to some authors, perception-based surveys involve some sampling problems, given by the fact that "the sample of respondents may actually be a result of environmental policies" (Becker and Henderson (2000), Botta and Kozluk (2014), p. 11).

In addition, complexity of environmental regulation makes sometimes difficult to disentangle pollution abatement costs from other costs, and sometimes for firms, it could also be beneficial to indicate wrong estimates. Finally, also the perception of the strictness of a determined regulation could be influenced by external factors and therefore be unreliable (Gallaher et al. 2006). One of such cases is when reporting is affected by business cycles: in periods of crisis, environmental regulation may be considered stricter than in other times (Brunel and Levinson 2013).

Shadow Prices and Performance Indicator Approach

Shadow prices are the costs of polluting that can be calculated from the firm's production function.

The production function becomes the starting point for the calculation of policy stringency; emissions would be considered as an element to

calculate the environmental stringency of regulation. The advantage of such approach is that, by looking directly at emissions, it considers the de facto situation and therefore assesses the real policy stringency and not the de jure one.

Performance indicators, as for the shadow price, look at the amount of emissions actually produced or at the pollution intensity in a specific media. However, contrary to the former approach, this one directly considers the amount of pollution produced as sign of environmental strictness.

Three main performance indicators have been used by the literature so far: emissions, energy consumption, and gasoline. The problem is that it cannot exclude multidimensionality and identification issues (Botta and Kozluk 2014). Most of the indicators quantify the problem to be addressed and not the stringency of environmental regulation. Identification problems are consistent, since the amount of emissions can be due to factors other than environmental regulations, which can be associated with the particular geographical structure, to the effect of other policies, and to other external factors (Albrizio et al. 2014). Also simultaneity can occur, since the amount of emissions could influence regulation itself.

Composite Measures

Composite measures seek to introduce multidimensionality into the analysis, trying not to eliminate the inevitable complexity of environmental regulation, but including it into an index. By doing this, composite measures are more complete, because they take into account all the factors of multidimensionality (Smarzynska and Wei 2001).

However, risks are very high: given the complexity of environmental legislation, the index must be adequately constructed and fine-tuned in order avoid methodological shortcomings, which in this case can be less evident and therefore more dangerous. Another disadvantage of indexes is that they are representatives of the only de jure situation. Such shortcoming is not negligible, since the enforcement and application of environmental regulation are crucial elements of environmental stringency (Sauter 2014, p. 8).

Choice of Indicators for Measuring Environmental Stringency

This section presents the indicators and proxies adopted by the literature for measuring stringency, namely, pollution abatement costs, the quantity of polluting emissions produced, and, finally, indexes, and then combines different measures in order to cover all possible elements of environmental stringency.

Pollution Abatement Costs

Environmental stringency has often been defined by using the proxy of the private sector's pollution compliance costs (Keller and Levinson 2002; Levinson 1999), namely, costs that firms face to comply with environmental regulation (Carraro et al. 2010). Compliance costs can take the form of environmental taxes, liability rules, emissions limits, and technological standards. They can also include permitting costs, regulatory delays, threat of lawsuits, and the redesign of a process or product (Levinson and Taylor 2008).

Some authors considered all types of pollution abatement costs and expenditures while others only a particular media (Brunnermeier and Cohen (2003).

The principal and most used method to calculate pollution abatement costs is based on surveys collected at regional and industry level about firms' costs on abating pollution. One of the most used and complete datasets is the PACE survey (Pollution Abatement Costs and Expenditures) which has been conducted for the first time on 1994 in the United States on annual data from 1973 and then repeated with few modifications on 1999 and 2005. It collects data on pollution abatement capital expenditures and operating costs mainly in the manufacturing industry of the United States. Other countries started collecting data on environmental expenditures. Above them are Canada, with its SEPE (*Survey of Environmental Protection Expenditures*), and the European Union with the Eurostat *Questionnaire on Environmental Protection Expenditure and Revenues* (EPE). Also the OECD has drafted a dataset on environmental protection expenditure and revenue.

Public Entities' Pollution Abatement Expenditures

The costs of the environmental effort made by the state or other public entities to enforce environmental protection do not use directly environmental regulation, but some proxies, and were more frequent some years ago, when environmental datasets were scarce and imprecise.

Proxies for public expenditure could consist in a mix between private and public expenditures (Pearce and Palmer 2001), in the state budget for enforcement and inspections (Gray 1997), or in the number of employees in environmental agencies in relation to the number of manufacturing industries (Levinson 1999).

The advantage of such approach is that it often includes the enforcement stage, which would allow assessing also the de facto scenario. However, if the aim is to assess the impact that environmental stringency has on firms, the method of looking at public expenses, which may include also environmental actions for consumers or householders, could bring to distorted results. Second, such proxies do not have a strong causal link with environmental stringency, making results not completely reliable.

Emissions

Polluting emissions can be used as a measure of stringency, in particular emissions in air and energy consumption. Scholars have considered the emission indicators in different ways; for some, a high number of emissions indicate that environmental regulation is too permissive; for others it demonstrates the tendency to a stricter environmental regulation. In particular, the literature on emissions as measure of stringency is divided in two branches: the first one considers regulation as exogenous, where environmental rules are given by external sources, such as a central government or an international organization. The second one considers emissions as a factor of production as any other in the firm's profit maximization dynamic.

With regard to the first case, some used the emissions' reduction as indicator for stringency (Smarzynska and Wei 2001; Gullop and Roberts 1983). For the second one, emissions produced by

firms are intended as a factor of production like any other, with the consequence that environmental stringency can be assessed through the amount of emissions that the firm decides to produce. This approach is based on the neoclassical assumption of the profit-maximizing firms: a firm that decides to maximize its profits would use its factors of production until the marginal revenue of the product equals its price (Levinson 2001).

Currently there is no global instrument that collects emissions for each country. Datasets on emissions are available only for Europe and the United States. In Europe the *European Pollutant Release and Transfer Register* (E-PRTR), which replaced the *European Pollution Emissions Register* (EPER), collected data on emissions into air and water from 2007 to 2014. In the United States, the US Environmental Protection Agency listed a new dataset, the *Trade and Environmental Assessment Model* (TEAM). TEAM considers emission produced as factor inputs in the production process, in that it combines these data with the industry sector, location, and trade agreements, being therefore able to assess the effect that a certain trade agreement could have on pollution discharge (Creason et al. 2005). Such database is available for three different periods, 1997, 2002, and 2007, only for the United States.

Indexes

Through the inclusion of individual indicators into a unique instrument, indexes can tackle many of the multidimensionality and complexity issues (Smarzynska and Wei 2001).

The first complete index is the one that Dasgupta et al. (2001) prepared in the occasion of the *United Nations Rio Conference on Environment and Development* on the basis of national reports prepared by public authorities. Public officials and NGO representatives had to answer questions regarding environmental awareness, the scope of environmental policies and regulations, the presence of control mechanism, and the implementation of environmental regulation. The analysis included four media (water, soil, air, biodiversity). However, such index was composed only for 1 year and afterward extended by Eliste and Fredriksson (2002) for the agricultural sector.

Another well-known index is the CLIMI (*Climate Laws, Institutions and Measures Index*) prepared for the European Bank for Reconstruction and Development (EBRD) in 2010 on the basis of the UN country reports and the UNFCCC (United Nations Framework Convention on Climate Change) reports. The CLIMI includes three dimensions: international cooperation, domestic climate framework, and fiscal or regulatory measures. The disadvantage of this index is that it considers only rules designed to address climate change and that it was drafted only for the year 2010 (Surminski and Williamson 2012).

The World Economic Forum used another method; businessmen and firm directors had to rate the regulatory stringency of the country in which the firm operates and to give them a grade from one to seven, where one represents very lax regulation and seven is the strictest environmental stringency. The result, called *Environmental Sustainability Index* (ESI), is complete, although it has the intrinsic shortcoming of being based on subjective perceptions and not on objective elements. The ESI has been used by Esty and Porter (2002) to build the *Environmental Regulatory Regime Index* (ERRI), together with the data on the Global Competitiveness Report 2001–2002 annual survey on business and government leaders (Esty and Porter 2005, p. 86).

EPI (Environmental Performance Index) measures environmental performance of countries in two main fields, human health and protection of the ecosystem. It is constructed through the use of 20 indicators reflecting national-level environmental data. The EPI represents a good source for panel data studies, since it examines more than 200 countries over 10 years. The benchmark for score application is the reaching of a “proximity target,” which corresponds to objectives fixed by international or national regulations, guaranteeing therefore a de facto assessment. Finally, the OECD has recently created a new index on environmental stringency, the *Environmental Policy Stringency Index* (EPS), which deserves a separate section for its peculiarities.

Media

Peter T. Leeson and Joshua Pierson
Department of Economics, George Mason
University, Fairfax, VA, USA

Abstract

Citizens can use media to solve political agency problems. To be useful for this purpose, however, media must be free. Freer media are strongly associated with superior political-economic outcomes and may be especially important to fostering political-economic improvement in the developing world.

Synonyms

[Mass media](#)

Definition

Media refer to means of mass communication such as the Internet, television, radio, and newspapers.

Media as a Mechanism for Controlling Government

Citizens in democratic regimes face a principal-agent problem with respect to their elected governors. While citizens empower political officials to wield government's authority in citizens' interests, left unchecked, political officials are tempted to use that authority for personal benefit. Democratic elections provide a means by which

citizens may hold elected officials accountable for their uses of government authority. However, citizens' ability to use the voting both for this purpose depends crucially on the extent of their knowledge about political actors' behavior and their ability to coordinate responses to such behavior.

Media can improve democracy's ability to help citizens address the principal-agent problem they face with respect to elected officials (Besley and Burgess 2001, 2002; Coyne and Leeson 2004, 2009a, 2009b, Leeson and Coyne 2007). By reporting on political actors' behavior, media inform citizens about the activities of political actors that are relevant for citizens' evaluation of such actors as stewards of citizens' interests. Moreover, by providing such information to large numbers of citizens, media can help coordinate citizens' responses to what they learn about political actors' behavior, rewarding faithful stewards of their interests through, for example, reelection and punishing bad stewards through popular deposition and/or refusal to reelect them.

Media can also help citizens address political agency problems through the foregoing channel by influencing who seeks political office. Where would-be political officials know that the private benefits of holding political office are low because of media-provided information and media-facilitated citizen coordination, individuals who desire political power to further their own interests rather than citizens' are less likely to seek elected office.

Media Freedom and Government Control of Media

The extent to which media can assist citizens in addressing the principal-agent problem they face with respect to political officials depends on media's freedom. Media freedom (or independence) refers to the extent to which government can directly or indirectly control the content of media-provided information reaching citizens. Where media freedom is higher, government's ability to influence the content of media-provided information is weaker and vice versa.

Government control of media can take many forms (Leeson and Coyne 2005). The most direct form is state ownership of media outlets. For example, all North Korean media outlets are controlled by the Korean Workers' Party or other appendages of the North Korean government. Elsewhere, media outlets are not owned by government, but are nevertheless owned by powerful people in government, creating a similar situation. Italy under the prime ministership of Silvio Berlusconi, who was also an Italian media mogul, is one well-known example of this phenomenon.

Government may also control media indirectly through ownership of media infrastructure. For instance, Romania's only newsprint mill was state owned for years following the end of Romanian communism. Similarly, the Associated Press of Pakistan is owned by the Pakistani government. In other countries, government exercises indirect control over media outlets whose financial positions depend on state-supplied income, such as revenue from government advertising.

Another important source of indirect government control of media is regulation of the media industry. Many governments require licenses for newspapers, television stations, and even journalists to operate and may use this power to restrict entry into the media industry to individuals who are friendly to the government and/or use the threat of license revocation to silence media critics.

Where government exerts significant influence over media and thus media are unfree, media's usefulness as a mechanism for assisting citizens to solve the agency problems they face with respect to their political officials is seriously impaired. Rather than monitoring political actors' behavior and reporting accurately on their uses of authority, media are likely to avoid furnishing citizens with such information or, worse still, furnish citizens with misleading information that benefit those in power. Uninformed or misinformed citizens find it difficult to use media-provided information to hold political actors accountable or to coordinate appropriate responses to such actors' behavior. Media's ability to effectively control government thus hinges critically on its freedom from government.

Media's Influence on Politics

A strong link exists between media and citizen knowledge. Citizens who are exposed to more media coverage of their local politics and who live in regions where media are freer are more politically knowledgeable than citizens who enjoy less media coverage of their local politics and who live in regions where media are less free. For example, in Eastern Europe, citizens who live in countries where media are freer are more likely to correctly answer basic questions about political representation in the EU, and in the United States, citizens who are exposed to more media coverage of their local politics are more likely to know their congressman's name (Leeson 2008; Snyder and Stromberg 2010).

A strong link also exists between media and political-economic outcomes. Across countries, freer media are associated with higher voter turnout and other forms of political participation (Leeson 2008). Freer media are also associated with higher income, more democracy, more education, and more market-oriented economic policies (Djankov et al. 2003). In the United States, congressmen whose districts receive better media coverage are more likely to vote in a manner consistent with their party's line, stand witness before congressional committees, and procure more spending for their districts (Snyder and Stromberg 2010).

Media's Role in Developing/Transition Economies

In developing and transition economies, media freedom is especially critical for political-economic development. Here, the problem of dysfunctional and corrupt government is pronounced, rendering media as a mechanism for controlling such malfeasance – a mechanism that, as indicated above, requires media independence – of particular importance.

Peru provides a striking example of how even a small amount of media independence can have a large effect on political-economic outcomes in the developing world (McMillan and Zoido 2004).

Despite the Fujimori government's bribe-secured control of all major media outlets in the country in the late 1990s, a small independent station that had not been bribed, Channel N, managed to acquire a recording of a high-ranking government official bribing an opposition politician to switch parties. Channel N repeatedly broadcast the video, and following suit, other channels began doing so too, eventually generating a popular backlash against the Fujimori government and the downfall of the corrupt Fujimori administration. In this case, the existence of only a single free media outlet proved critical to exposing political malfeasance and catalyzing the removal of a self-serving government.

In Russia, in contrast, a dearth of media freedom has prevented media from controlling government. Under the Soviet regime, government completely controlled Russian media, which served as little more than tools for government propaganda. During glasnost and perestroika, laws guaranteeing media independence were passed, and Russia's media appeared to become significantly freer. Ties between Russian media and political elites were never completely severed, however, and Russian media independence suffered major blows during the economic downturn of the early 1990s.

During this period, Russian media circulation and revenue plummeted. In consequence, many media outlets became dependent on state subsidies. Today, the Russian government commonly interferes with freedom of the press (on an important exception, see Enikolopov et al. 2011). Owners of media outlets that are critical of the government are threatened with jail time or forced to sell, and journalists who are critical of the state have been intimidated and even killed (Zassoursky 2004). Government's influence on media in Russia has contributed to Russian political actors' ability to wield public office for private gain.

Medical Liability

Ben C. J. van Velthoven and
Peter W. van Wijck
Leiden Law School, Leiden University,
Leiden, The Netherlands

Abstract

This article concerns the preventive effects of medical liability. On theoretical grounds it is argued that medical liability does not necessarily lead to a socially optimal level of precaution, because the incentives are distorted in various ways. Since the 1970s, US states have enacted a variety of reforms in their tort

systems. This variation has provided highly useful data for empirical studies of medical liability issues. For one thing, it has become clear that only some 2% of the patients with negligent injuries gets compensation. The empirical evidence nevertheless suggests that medical liability pressure does affect the behavior of healthcare providers to some degree. It has a negative effect on the supply of services, and it encourages the ordering of extra diagnostic tests. At the margin, medical liability law does seem to have some social benefits that offset reasonable estimates of overhead and defensive medicine costs.

Definition

Medical liability essentially is tort law applied to healthcare providers. If negligent behavior of a healthcare provider causes harm to a patient, the healthcare provider has to pay damages to the patient. In this way, medical liability may lead to compensation of harm. Medical liability may also influence incentives to take care and consequently influence the probability and the size of harm. In the Law and Economics literature, the focus is on this preventive function.

Introduction

Medical treatment is supposed to improve the patient's health. But there is no guarantee. The patient's condition, bad luck, and medical errors may stand in the way of recovery. As adverse events occur within a market-type relationship, physicians and patients could write a complete contract to lay down the mutual understandings with respect to the specifics of the treatment and set the price of the contract accordingly. But this manner of controlling the level of care fails because of asymmetric information (Arlen 2013). Patients just do not know whether a physician delivers medically appropriate care. Moreover, individual bargaining about the level of care and the corresponding price brings along huge transaction costs and is even totally impossible in the

case of emergencies. Fortunately, society has several other institutions available for the control of medical care. The government can centralize control by installing a regulatory body to enforce safety standards. State licensing, disciplinary boards, and hospital credential committees may also motivate physicians to act with proper care. Here we focus on medical liability (see also Van Velthoven and Van Wijck 2012).

Medical liability has received much attention in the Law and Economics literature in the past decades. The main reason is that since the 1970s, the USA has experienced three medical malpractice crises, periods characterized by significant increases in the premiums and contractions in the supply of malpractice insurance. In response to these crises, US states have enacted a variety of reforms in their tort systems. As a result, the USA has seen a considerable variation, across time and space, in the pressure of the medical liability system on health care providers. That variation has provided highly useful data for empirical studies into the actual working of the tort law system. For the same reason, most of those studies focus on the USA.

The Standard Tort Model Applied to Medical Liability

In the economic analysis of tort law, a fundamental distinction is made between unilateral and bilateral accidents (Shavell 2004). Medical injuries can generally be taken to be *unilateral accidents*. A physician who wants to reduce the probability and severity of medical injury can increase the number of visits provided to his patient, perform additional diagnostic tests, refer the patient to a specialist, opt for more or less invasive procedures, and/or take more care in performing surgery. The patient is usually unable to influence expected harm from a medical injury.

Figure 1 presents the standard tort model for a unilateral accident case (Miceli 2004, pp. 42–45). As the (potential) injurer raises the level of care by taking additional precautionary measures, his *costs of care* increase. But at the same time, there is a reduction in the *expected harm* for the

Medical Liability,
Fig. 1 Efficient care

(potential) victim, as additional care may reduce the probability and/or the severity of accident losses. The social optimum is obtained if the expected total costs are at a minimum. The socially optimal level of precaution is frequently referred to as the *efficient level of care*.

Medical liability law quite universally holds an injurer liable for accident losses that are attributable to *negligence*. The negligence rule presupposes a norm of *due care*, specified by statutory law or jurisprudence, for the precautionary measures that the injurer should take at a minimum. If the injurer's level of care falls short of this minimum, the injurer is negligent and will be held liable for accident losses. On the other hand, if the injurer's level of care equals or exceeds the due care norm, accident losses will remain with the victim. In this way, the negligence rule creates a discontinuity in the injurer's expected costs at the level of due care, as shown by the fat curve in Fig. 2. The injurer minimizes his costs by just taking precautionary measures in conformity with the due care norm.

Whether the injurer will act in a socially optimal manner then depends on the proper choice of the due care norm. He will take socially optimal precaution if the level of due care coincides with

the efficient level of care, as in Fig. 2. If the due care norm is set below (above) the efficient level of care, the personal incentives will generally lead the injurer to behave in a suboptimal manner by taking too little (too much) precaution.

Apart from the level of care chosen by the (potential) injurer when engaging in a certain activity, total costs for society also depend on his *number of activities*. Under negligence, when the injurer conforms to the due care norm, he cannot be held liable for any accident losses. Consequently, a non-negligent injurer is not confronted with the full social costs of his activity. This negative externality may lead the injurer to undertake too many activities from a social point of view.

Problems in Applying the Standard Tort Model to Medical Liability

In practice, a number of specific characteristics of medical care pose serious problems to a straightforward application of the standard tort model.

Uncertainty About Due Care

The standard tort model suggests that injurers can be induced to provide socially optimal care if law

Medical Liability,**Fig. 2** Efficient care under the negligence rule

sets due care at the efficient level. This simple rule, however, is not easily met in the health care sector:

- It is difficult to determine the efficient level of care, even for specialists in the field. Instead, the courts generally evaluate the conduct of physicians in terms of customary standards of practice within the medical profession or a significant minority of such professionals (Weiler et al. 1993, p. 8; Danzon 2000, p. 1343; but see Peters (2002) for a somewhat different reading).
- Physicians have no exact insight into the due care norm that will be applied by the courts when confronted with a claim.
- In each specific case, the court has to decide whether the physician has been careful enough. Even if the due care norm is right, the court may err in its decision, as the information presented to the court will generally be incomplete and subject to mistakes in interpretation. Consequently, physicians do not know exactly how careful they have to be in order to escape liability.

Calfee and Craswell (1984) have studied the consequences. If there is uncertainty about the due care norm and its application in court, there is a

chance that a physician who has taken sufficient care may still be held liable for damages. The physician can try to reduce that chance by *over-complying*, that is, by raising his level of care beyond due care.

Ethical Norms

Most physicians swear (some variant of) the Hippocratic oath to use their best ability and judgment in treating their patients. This may affect the ethical values in the profession in such a profound manner that all other (financial) considerations are rendered more or less futile. If so, the result would be overcompliance, that is, delivering more care than strictly necessary.

Who Bears the Costs of Care?

The standard tort model starts from the premise that the costs of care are borne by the injurer. This is, however, not self-evident in the health care sector, as physicians are generally paid on a fee-for-service basis. Moreover, most patients carry a health insurance policy. When a physician decides to raise the level of care, he will not have much trouble in charging the additional costs to his patient, who will forward the bill to his insurance company.

Of course, this financial incentive to provide too much care will be mitigated if healthcare

services are financed in a different way, which hinders or prevents the passing on of additional care costs. One can think of: pure salary payment, capitation payment, or managed care plans (Glied 2000).

Litigation Problems

The standard tort model takes it for granted that the injurer pays damages, once he is found negligent. In general, however, this payment will not be made spontaneously. First, the victim has to decide whether it is in his interest to file a claim. The patient may be unaware of the negligence of his physician, the decision of the court may be too uncertain, the litigation costs may be too high, or the financial means of the victim may be insufficient. Second, if the claim is below a threshold of, say, \$250,000, the patient may not be able to find an attorney willing to accept his case on a contingent fee basis (Shepherd 2014). Third, even if a claim is filed, parties may decide to settle the case in order to save on litigation costs. If the case is settled, damages will not amount to a full compensation.

The implication of all this is that expected damage payments are smaller than the expected harm of the injurer's behavior. The result is a tendency toward insufficient care.

Liability Insurance

Most, if not all physicians, carry a liability insurance policy (GAO 2003, p. 6). By shifting the burden of the damages, liability insurance lowers the injurer's costs of insufficient care (Zeiler et al. 2007).

In theory, experience rating can redress this tendency. Experience rating refers to a variety of schemes that see to it that liability insurance premiums reflect each insured's expected loss (Danzon 2000, p. 1160). This is mostly done by varying premiums with past claims or loss experience. Shavell (1982) has shown that insurance need not interfere with the incentive effects of liability if premiums are perfectly experience rated. But experience rating is more easily said than done in the case of medical care. Medical malpractice claims occur too infrequently to give insurance companies enough information to

reliably set premiums in accordance with individual physician's care levels.

Medical liability insurance, however, does not completely eliminate incentives to take care. Malpractice may affect the physician severely, even if he is fully insured against the financial consequences, as claims also bring along other kinds of costs. The defense takes quite a lot of precious time, the experience is rather unpleasant, and it may cause serious reputational harm (Weiler et al. 1993, p. 126).

Patient Safety Investments

In the standard tort model, the individual physician makes a more or less informed decision on how to treat each particular patient. But that model does not fully capture the causes of medical negligence (Arlen 2013). Many medical injuries occur accidentally when physicians unknowingly err in the diagnosis and the selection of treatment or when the hospital equipment and staff fail in delivering the treatment. The probability of such errors can be reduced by investing in expertise, healthcare technology, and personnel. But such patient safety investments generally fall outside the factors courts consider in determining whether a physician has been negligent. The incentives for the physician, and the hospital, to invest in patient safety are therefore suboptimal.

Conclusion

Medical liability does not necessarily lead to a socially optimal level of precaution, because the incentives are distorted in various ways. For one thing, physicians generally do not bear the full accident losses of insufficient care. This distortion may act as an invitation to physicians to take less care than legally required. Still, the nonfinancial consequences of liability (time, hassle, reputation loss) and ethical considerations may provide some counterweight. Other distortions provide incentives to act on the safe side of the due care norm. Physicians generally do not bear the (full) costs of care due to specific methods of financing in the healthcare sector. And there is uncertainty about the due care norm and its application by the courts. On balance, there might be a bias toward excessive care.

Defensive Medicine

In the USA, the conviction has taken root among physicians and their liability insurers that the medical liability system has gone wrong. It is argued that the pressure has evolved to such a level that it has given rise to *defensive medicine*. The most common definition (OTA 1994, p. 21) reads: “Defensive medicine occurs when doctors order tests, procedures, or visits, or avoid high-risk patients or procedures, primarily (but not necessarily solely) to reduce their exposure to malpractice liability.” According to this definition, defensive medicine can take two forms. *Positive* defensive medicine involves supplying care that is not cost effective, unproductive, or even harmful. *Negative* defensive medicine involves declining patients that might benefit from care. It also includes physicians deciding to exit the profession altogether.

Our discussion of the standard tort model demonstrates that positive defensive medicine will not necessarily be found in practice, as liability pressure on the level of care is working in two opposite directions. Thus, the question whether physicians take excessive care is really an *empirical* question. Second, if malpractice pressure does produce a bias toward excessive care, it is excessive in comparison to the *due care* norm. But it is not at all certain that the due care norm has been set equal by law to the efficient level of care. That leaves the possibility, even if empirical research finds proof of excessive care, that level of care still falls short of the socially optimal amount (Sloan and Shadle 2009, p. 481).

The concept of negative defensive medicine is related to the number of activities, referred to earlier. If a physician takes at least due care, he will not be liable for any accident losses, which might give him the incentive to accept too many patients from a social point of view and/or to stay too long in the profession. On the other hand, the simple fear of malpractice claims, even if unwarranted, and the corresponding threat of time and reputation loss may work in the opposite direction. Hence, the existence and scope of negative defensive medicine is, once again, an

empirical question. Moreover, note that the interpretation of the findings may change if physicians exercise insufficient care. Then, malpractice law helping patients to file claims and to obtain damage payments may give negligent physicians a good reason to revise their conduct, not only by raising the level of care but also by accepting fewer patients or by early retiring. Such a behavioral response might be very welcome from a social point of view.

What makes the interpretation of the findings even more complicated is the interaction between the defensive medicine that may follow from medical liability pressure and the *offensive medicine* that is induced by physicians’ financial incentives (Avraham and Schanzenbach 2015). When physicians have the discretion to choose among different treatment regimens and health insurance adequately covers their patients’ medical costs, physicians may be tempted to opt for the more invasive procedures, which in general will be the more remunerative ones. But more invasive procedures are also riskier. Hence, medical liability pressure may counteract the tendency toward offensive medicine.

Medical Liability Litigation

This section surveys the empirical evidence concerning medical liability litigation. The different layers of the dispute pyramid (Galanter 1996) are discussed one by one.

Three large-scale surveys of medical records of hospitalized patients in the USA have investigated the incidence of injury due to negligent medical care. In the most recent survey in Utah and Colorado in 1992 (Studdert et al. 2000), it was found that 2.9% of all hospitalized patients had an adverse event that was related to medical care. Some 0.8% of the patients suffered a negligent injury, where negligence was defined as treatment that failed to meet the standard of the average medical practitioner. No attempt was made to define negligence by weighing marginal costs and benefits of additional precautions. So, the resulting count of negligent injuries does not necessarily correspond to inefficient injuries.

The second layer of the dispute pyramid discloses how many of the injury victims take steps to obtain compensation. In the Utah and Colorado study, only 3% of the patients who were identified as having sustained a negligent injury filed a malpractice claim. But there was also a significant number of “false positives.” Aggregate data from insurers’ records pointed out that a substantial number of malpractice claims do not correspond to an identifiable injury due to negligent medical behavior. Of course, all these plaintiffs may still have filed the claims in good faith, from a state of imperfect information, leaving it to the tort system to separate the rightful claims from the non-deserving ones.

The third layer of the dispute pyramid discloses how filed claims fare in the tort system. In a large study of malpractice claims closed between 1984 and 2004, Studdert et al. (2006) found that 61% of claims could be associated with injury due to medical error, while 39% of the claims had no merit. Only 15% of all the claims were resolved by trial verdict; the rest was settled in the “shadow of the law” or dropped. Most of the claims involving injuries due to medical error (73%) received compensation; most claims not involving medical error (72%) did not receive compensation. Moreover, when claims involving error were compensated, payments were significantly higher on average than were payments for non-error claims.

With respect to the payment amounts, two observations are in place. First, compensation in most cases falls short of plaintiff’s losses, especially for more serious injuries (Sloan and Chepke 2008). Second, the costs of administering the tort system (legal expenses, overhead costs) are considerable. According to calculations by Mello et al. (2010), it costs US society overall more than \$1.70 to deliver \$1 of net compensation.

The tort litigation system is not perfect, then. It sometimes makes physicians – or their insurers – pay damages for non-negligent care. But the system is clearly not a random lottery (see also Eisenberg 2013). Negligent injuries are at least ten times as likely to end up in compensatory payments as non-negligent injuries. As a result, there is a strong association between the

numbers of adverse patient safety events in hospitals and paid medical malpractice claims (Black et al. 2017).

More disturbing for the proper working of the system is the high rate of “false negatives.” From the figures above, it follows that just some 2% of the patients with negligent injuries gets compensation, mainly because a large fraction of valid claims is not filed, but also because not all valid claims that are filed get honored. And even that 2% is quite likely a serious overestimation, as an observational study of healthcare providers has shown that hospital records may miss over 75% of serious medical errors (Andrews 2005). Combining the high rate of false negatives with the finding that compensation generally falls short of victims’ losses suggests that the deterrent function of the system must be rather limited.

Tort Reform

In the introduction, it was noted that the USA experienced three “crises” in the medical liability insurance market in the past decades. These were periods of deterioration in the financial health of carriers, followed by sharp increases in premiums and contractions in supply. This is not the place to delve deeply in the causes of these crises (cf. Danzon 2000; Sloan and Chepke 2008). But one factor can be singled out: the “long-tail” character of this line of insurance. Claims may be filed many years after an adverse event causes injury. And from there, it may take many more years before the insurance company finally knows how much compensation it has to pay. If, for whatever reason, there is a gradual rise in claim frequency and/or in average payments, for instance, because of pro-plaintiff adaptations in common law doctrines or because patients are becoming more assertive toward healthcare professionals, insurance companies will tend to lag behind. They will develop unexpected losses, and over-react in raising premiums and curtailing supply.

In response to the malpractice crises, most US states have adopted tort reform measures. The objective of these measures is to reduce the

overall costs of medical liability. The extent and specifics of tort reform vary from state to state (cf. www.atra.org). Some reforms aim at a reduction of damage awards, other reforms make it more costly or difficult to file tort cases in the first place. The most commonly adopted tort reforms are: caps on non-economic damages, pretrial screening panels, contingency fee reform, joint-and-several liability reform, collateral source rule reform, periodic payment, and shorter statutes of limitation. The effects of these tort reforms on the frequency and the size of claims and on malpractice insurance premiums have been studied extensively. A detailed review by Mello and Kachalia (2016) concludes that there is no convincing evidence that any other reform than caps on non-economic damages has had a significant impact. As to damage caps: the weight of the evidence suggests that they reduce claims frequency, achieve substantial savings in average damage payments, and modestly constrain the growth of malpractice insurance premiums. So one would be tempted to conclude that at least this specific kind of tort reform can help to relieve malpractice pressure, if so desired. But even that conclusion is called into question. Zeiler and Hardcastle (2013) point out that thus far no one study has employed a consistently solid set of empirical research methods.

More recently, also other kinds of reform measures have been proposed, such as apology laws and disclosure programs, presuit notification periods, health courts, and safe harbors for adherence to evidence-based practice guidelines. As these reforms are relatively new in use, if at all, the empirical literature on their effects is as yet very small.

Preventive Effects of Medical Liability

It is an empirical question whether medical liability leads physicians to take appropriate precautions or to engage in defensive medicine. In the literature, four main research lines can be distinguished.

The first line of research surveys physicians and asks their opinion on the role of malpractice

pressure in clinical practice. These studies (e.g., Carrier et al. 2010) unequivocally point out that concerns about malpractice liability are pervasive among physicians. Indeed, in a survey of high-risk specialists, 93% of the interviewees reported practicing defensive medicine (Studdert et al. 2005). Yet, the results should be handled with caution. First, the relationship between perceived malpractice threat and objective liability risk is found to be very modest. Physicians systematically overestimate the risk that malpractice action will be brought against them. Second, the relationship between malpractice threat and clinical response is a self-reported one.

The second line is about the actual relevance of positive defensive medicine. How do treatment choices by physicians, and the health outcomes of their patients, respond to malpractice pressure? Much attention has gone to obstetrics, the field that has one of the highest levels of premiums, claim frequency, and damage payments. Typically, studies examine the impact of tort reform on cesarean section rates. Some studies have also looked at the impact on infant health at birth. Overall, the results are inconclusive. Thus far, there is no decisive evidence for positive defensive medicine in obstetrics (Eisenberg 2013). Some other studies focus on cardiac illness or take a look at broader sets of ailments or total healthcare expenditures. The results are mixed. As far as physicians are found to practice positive defensive medicine, the excessive care appears to be related to rather elementary diagnostic tests such as imaging, not to major surgical procedures. The overall picture is that the total effect on healthcare costs, if any, is rather small (Thomas et al. 2010).

The third line of research is on negative defensive medicine and analyzes how tort reform affects the supply of healthcare services. The evidence with respect to obstetrics is mixed. Other studies analyze the overall supply of physician services. Their results generally point out that higher malpractice pressure tends to diminish healthcare supply, be it the number of physicians, statewide or in local areas only, or their hours worked. That finding seems to be proof of negative defensive medicine. But note that the

interpretation is not so obvious. A smaller supply of physicians in itself can be presumed to contribute negatively to social welfare, but there may also be offsetting effects if the quality of the physicians that stop or reduce their practice is below average. Indeed, Dubay et al. (2001) and Klick and Stratmann (2007) find no evidence that the changes in supply had negative health effects.

Finally, an interesting new line of research tries to assess the preventive impact of medical liability forces by drawing on variations in the negligence standard facing physicians. The majority of US states have over time moved from a due care norm based on the customary practices of local physicians to a national standard of care. The first empirical results (Frakes and Jena 2016) indicate that treatment quality improves when the clinical standards go up.

Cost-Benefit Analysis

Empirical evidence suggests that medical liability pressure does affect the behavior of healthcare providers. It does seem to encourage the ordering of extra diagnostic tests, and it tends to reduce the supply of services. However, positive defensive medicine does not have a clear-cut effect on health. If the additional tests and procedures have any value, it is only a marginal one. Furthermore, changes in the supply of services do not affect health adversely. This suggests that the physicians that are driven out of business have a below average quality of performance. Hence, at the margin, medical liability law may have some social benefits (see also Zabinski and Black 2015).

These benefits must be weighed against the costs of the additional tests and procedures. The costs of administering malpractice claims also deserve attention. Both Danzon (2000) and Lakdawalla and Seabury (2012) have made a shot at a back-of-the-envelope calculation of the costs and benefits. They conclude that under quite general assumptions, the benefits of even a modest reduction in injury rates suffice to offset reasonable estimates of overhead and defensive medicine costs. This follows from the large social costs

of medical injuries and the low rate of claims per negligent injury.

Yet, instructive as these calculations may be, they mainly have a heuristic value. First, a full cost-benefit evaluation of the medical liability system is impossible in the current state of affairs. Second, even if the marginal benefits of the current system do outweigh the costs, the search for improvements and alternatives is open (see, e.g., Sloan and Chepke 2008). It is argued that the impact of the medical liability system can be substantially improved by shifting liability from the individual physician to the medical entity involved (Arlen 2013) and by restructuring the financial incentives in the healthcare sector (Frakes 2015).

Medical Malpractice

Veronica Grembi

Copenhagen Business School, Copenhagen, Denmark

Abstract

MM first came to the attention of policy makers primarily in the USA where, from the 1970s, healthcare providers denounced problems in getting insurance for medical liability, pointing out to a *crisis* in the MM insurance market (Sage WM (2003) *Understanding the first malpractice crisis of the 21st century*. In: Gosfield AG, (ed) *Health law handbook*. West Group, St. Paul, pp 549–608). The crisis was allegedly grounded in an explosion of requests of compensations based on suffering iatrogenic injuries. Since then, MM problems have been identified with scarce availability of insurance coverage and/or its affordability, the withdrawal from the MM insurance of commercial insurers, the growth of MM public insurance or self-insurance solutions, the choice of no-fault

rather than negligence liability, the adoption of enterprise liability for hospitals, the concerns for defensive medicine, and the implementation of tort reforms so to decrease MM pressure (i.e., frequency of claims and the levels of their compensation) on healthcare practitioners. While the initial contributions to the topic are mainly based on the US healthcare and legal system experience, a growing attention to these problems has raised in the last decades also among European countries (Hospitals of the European Union (HOPE) (2004) Insurance and malpractice, final report. Brussels, www.hope.be; OECD (2006) Medical malpractice, insurance and coverage options, policy issues in insurance n.11; EC (European Commission, D.G. Sanco) (2006) Special eurobarometer medical errors).

Definition

Medical malpractice (MM) deals with two kinds of problems that healthcare providers, patients, and insurance companies have to deal with in different legal and healthcare systems: (1) medical errors without legal consequences and (2) medical errors with legal consequences. The contributions to this field aim at defining an efficient level of (1) and to efficiently deter and compensate (2). Empirical evidence on the actual trends of medical errors, medical liability claims, and the link of the former and the latter with both the trend of MM insurance premium and the treatment decisions of healthcare providers are not always unambiguous.

Medical Malpractice

Starting from the 1970s, healthcare practitioners, lawyers, and insurance companies in the USA experienced so-called crises of MM. The characteristics of the first crisis, joint to those which followed during the 1980s and the beginning of the New Millennium, could be summarized as follows (Mello et al. 2003): first, an increase in MM claims not always justifiable by a similar increase in medical errors; second, an increase in

MM premium for healthcare providers joint to the scarcity of available insurers in the market; and third, the tendency of healthcare practitioners to adopt behaviors which can minimize the probability to be targeted by a legal claim but not the probability of an error or bad quality medicine, also known as defensive medicine. All in all, there is an increase in legal, insurance, and healthcare expenditures, which have consequences for the quality of the delivered healthcare (Arlen 2013). Similar concerns and complaints have started to be common also among several European countries, notwithstanding their quite different healthcare and legal systems compared to the USA. The contribution of the economic analysis of law to this subject is at first a theoretical analysis of the role of legal rules as incentivizing mechanisms to achieve efficiency across different institutional settings. As such, the law and economics of MM provides a common ground of theoretical elements, which, in time, have been accompanied by the production and discussion of often controversial empirical evidence.

From a theoretical viewpoint, MM has to do with the definition of the *efficient* medical error as it has been shaped by the contributions of the economic analysis of tort law (Shavell 1987; Arlen 2013). According to this approach, the goal of legal rules is not to reduce the probability to have errors to zero, but to deter *inefficient* errors and compensate the innocent victim of an *inefficient* error. Suppose that the probability that an error i takes place is equal to p_i and that in case i happens, victim v will suffer damages equal to D (both economic and noneconomic). The expected damages are equal to $p_i D$. The healthcare provider-potential injurer in this framework can decrease p_i investing in precaution, which will cost her c , with c increasing as p decreases (i.e., $c(p)$). The efficient level of precaution minimizes the sum of the expected damages, $p_i D$, and the cost of precaution, c . For that optimal level of precaution, let us call it x^* , the level of medical errors allowed into the system is considered efficient and expected to be different from zero (i.e., the social optimum). We have tried to summarize this basic intuition in the diagram presented in Fig. 1. Areas B and C represent the

Medical Malpractice, Fig. 1 Relationship between MM claims and medical errors

universe of medical errors within a given institutional setting. Consistently with what we have just stated, legal rules need to define the prerequisites to put an error in either B or C: in an ideal setting, if the legal system is properly designed, an error in C is efficient and an error in B is inefficient, and the dimension of B has to be efficient in a social welfare perspective.

In the same setting, a policy maker can set the boundaries between C and B using either a negligence/fault rule or a strict liability/no-fault rule. In the first case the stress is on the threshold of precaution below which the potential injurer is held liable. As in the case of a car accident liability, a speed threshold is set and if an accident occurs, you will be liable only if your speed was higher than the imposed limit. In the second case (i.e., No Fault) a key role is played by the causation link between the negative outcome and the injurer action. In other words you are responsible if you injure somebody in a car crash, but you are not accountable for injuries that your potential victim got before the crash. Both liability rules find a place in the realm of MM. Both can generate less than or more than efficient precaution in the real world.

The problem of transposing the basic liability model on medical “accidents” is that it is not always clear how precaution is related to expected outcomes. While in the case of a car accident, the sequence is clear: you speed, the car crashes, and a person that before the impact was sound is now injured. In the case of a medical accident, there might be a less clear sequence. A physician does not take the necessary precaution; she treats a sick patient, and the sick patient does not heal.

Unfortunately it is not so simple. It could well be that the sick patient heals or that he/she heals but it takes a week more than expected. In other words, defining precaution in this context is not so straightforward. We could think about appropriate hygienic conditions and basic working environment, but then the real issue at stake is more related to the case of a misdiagnosis or to a mistreatment and to the elements causing the former rather than the latter. But this is a case-by-case call. Hence, the problem is how we define a case-by-case standard of care. For instance, the consensus on precaution levels (or treatment choices) can be high on routinely practiced interventions and low on more complicated procedures. Whenever the standard of care to be adopted is not accurately specified, the system might end up characterized by less or more than efficient standard of care. One consequence is the so-called defensive medicine, a modification in care decisions triggered by MM pressure (i.e., frequency of claims and the levels of their compensation), which can be positive or negative (Danzon 2000; Kessler 2011). Positive defensive medicine consists in the use of treatments or diagnostic tools that are not able to improve the quality of care delivered to patients, but apt to decrease the probability to be targeted by a legal claim. It is a form of supplied induced demand: if the patient has the same information that her physician has, she would have not chosen the recommended care. Negative defensive medicine coincides with forms of cream skinning of patients or procedure. Less risky patients are selected into treatment so to decrease the probability of negative outcomes, and needed risky treatments can be avoided due to the fear of the legal consequences.

A second challenge to the liability model is represented by the organization of the healthcare system. The healthcare organization matters as much as legal rules, to achieve or miss an efficient level of precaution. For instance, a physician could have different incentives to practice defensive medicine depending on whether she is employed by the hospital or she is an independent practitioner. Finally, the possibility to buy insurance for medical liability and the type of insurance

can alter the structure of incentives produced by the legal rules. Insurance is available in a private/commercial form, often not experience rated, or in a public form (However, the distortions generated by the insurance for medical liability should be attenuated by reputational concerns, supposedly more for private rather than public healthcare providers). Forms of public insurance can come together with hospital self-insurance within a public healthcare system, or through a specific public fund. Public coverage can solve some of the problems connected to the insurance market for MM, but they have the potential to generate new kind of problems, such as common pooling of individual risks among the covered healthcare providers, basically incentivizing under-precaution.

In other words the perceived costs/benefits of taking precaution are affected by the certainty of the standard of care, the organization of the healthcare system, and the availability and form of insurance for MM. In principle a fault system with a private MM insurance and no unanimity on the standard of care could trigger positive defensive medicine. Such consequence could be mitigated if the practitioner is not directly responsible, but as an employee of a hospital is covered by an enterprise liability. However, in this case less than efficient precaution could be held. For the same token, a no-fault liability system with private MM insurance could more easily generate negative defensive medicine behaviors. A public insurance scheme could cope with this problem, but again at the expenses of incentive to take precaution. In reality, MM liability comes together with other institutional elements able to affect the structure of incentives foreseen by the economic analysis of law, and this is why defining the best solution according to a social welfare perspective is a debated issue, which needs to be supported by sound empirical work.

Empirical evidence on MM can be grouped in two sets: (1) evidence on the incidence of medical errors, useful to assess the dimension of the iatrogenic injury problem, the relationship between actual errors and claims, and the inner causes of medical errors (Weiler et al. 1993; Nys 2009), and (2) evidence on the effectiveness of

policies directly or indirectly oriented to decrease MM pressure on the healthcare providers as well as changing the structure of costs and benefits of potential claims (i.e., tort reforms) on (a) liability measures such as the frequency of MM claims and medical liability insurance and (b) care-related measures as defensive medicine, the quality of care, or the supply of physicians (Kachalia and Mello 2011; Kessler 2011).

Overall, the empirical assessment of MM is not an easy task. The number of claims filed every year against hospitals and medical practitioners might not necessarily stem from negligent mishaps, while many negligent behaviors and their outcomes are not actually prosecuted (Weiler et al. 1993). Defining for empirical purposes, a medical error or, more properly, an injury due to unacceptable medical negligence is not a straightforward task either: as stated it requires an implicit assumption on the expectations of the outcome of a specific treatment or procedure conditional to many variables describing the conditions of the patient (Danzon 2000). Expectations on a normal distribution of outcomes are not always set before running empirical investigations. The US studies are usually the benchmarks in this field. The first surveys had been run during and in the aftermath of the first malpractice crisis. The 1974 California Study is worth mentioning even though the most famous work is definitely the 1984 Harvard Study, dealing with New York Hospitals data (Weiler et al. 1993). Later on similar initiatives have been undertaken in other countries: the 1995 Australia Study on healthcare quality had been drawn on the Harvard blueprint (Weingart et al. 2000), and a similar approach has been followed in a 1998 study on New Zealand public hospitals (Davis et al. 2002), a 1999–2000 English study (Vincent et al. 2001), a 2004 Dutch study (Zegers et al. 2009), and a 2005 study on Spanish hospitals (Ministero de Sanidad Y Consumo 2006), just to mention a few. Overall they assess a level of incidence of adverse events between 2.7% and 16.6% for the public systems and between 3.7% and 17.7% for the American system (Weiler et al. 1993; Andrews 2005). Around half of them are judged to be

preventable¹. The idea underpinning risk/error management solutions is that bad things do not happen to bad people (Reason 2000); rather “it is weak systems that create the conditions for error” (Department of Health 2002). According to this managerial awareness, the Department of Health in the UK has promoted initiatives to implement the error report system between local and national level. In the aftermath of the 1999 Institute of Medicine Report *To Err is Human: Building a Safer Health System*, many countries felt the urgent need to introduce a “safety culture” within their health systems (Barach and Small 2000). Improve error disclosure, a better interaction among different branches of the same health system, and homogenization of some basic medical procedures are among the undertaken steps. Both insurance companies and medical associations have stirred up such urgency. Additionally, it has been frequently recalled the importance of looking to “high reliability organizations” (i.e., aviation, nuclear power plants) in order to import or shape risk/error management policies that had been widely tested, especially to deal with near misses. Leape and Berwick (2005) undertook a study on the changes in hospital practice to improve safety in the USA 5 years after the publication of *To Err is Human*. Although a national inquiry is still missing, a local level analysis has been characterized by a decrease of adverse drug-related events and infections. Similar investigations (*how* the policy enforcement has effectively reduced *what*) would be desirable in other countries. An accurate analysis of the administrative costs of such policies is missing both at local and national level.).

However, the adopted definition of injury/adverse event, starting with the US studies, has been quite criticized. Identifying an injury as “any (negative) deviation from the expected outcome” and adverse event as “an unintended injury that

was caused by medical management and that result in measurable disability” (Danzon 2000, p. 1352) has been judged either a too broad or a too narrow approach. Some authors, generally not economists, think that such definitions do not allow the inclusion of errors that are not associated to any injury either because the doctors were extremely lucky (and the patients too) or because the doctors could catch the mistake in time (again, a matter of luck) (Weingart et al. 2000). According to this interpretation, the findings should be regarded as the lower bound of a much striking number. Other authors, generally economists, disagree with the previous view, arguing against a loose definition used in the recalled studies and raising the problem of the efficient error, that for which the cost of precaution is equal to the expected damages. In other words, since we have not decided *ex ante* what is the efficient slot of errors related to the practice of a high risk activity as healthcare, we could not state for sure whether those numbers represent efficient or inefficient errors. Consequently, the empirical findings could be viewed as an exaggerated upper bound of a much less sensational phenomenon. Is the “preventable” number of adverse events really representative of inefficient errors? Does “preventable” mean efficiently preventable (precaution costs < potential benefits)? These questions still need to be addressed in practice.

Despite the fact that the two views are clashing, they are extremely useful to get a flavor of the range of factors we should evaluate and weigh when we try to empirically assess the incidence of iatrogenic injuries. A further contribution in this respect comes from a strand of less sound econometric analysis, run sometimes by physicians, which proposes an issue raised by other studies in the field: why injured patients do not always file a claim? Michael Rowe (2004), for example, supports with several case studies the evidence that the probability that a patient will file a suit will decrease whenever he/she has been told about the error. Paradoxically, wards – who are more exposed to the eventuality of error like Emergency Rooms, but where the doctors have a closer and constant supervision of the

¹It might be worthwhile to mention the “risk management” approach on this point. Indeed a central issue is “whether negligent injuries are caused largely by occasional inadvertent lapses of many, normally competent providers or by a minority of incompetent, physicians and low quality hospitals” (Danzon 2000)

patient – tend to get less malpractice suits than other safer wards.

A final concern related to the assessment of medical errors is how we should judge the relationship between errors in medicine and quality of the healthcare service. This is in a way a sort of paradox. The actual improvement in the medical technology and a better knowledge of tackling endemic pathologies, considered fatal just a couple of decades ago, have transformed medical risk in two ways. On the one hand the new technology creates risks that did not exist previously (This belongs to the well-known path of human progress. The automobile invention had caused both development and accidents!), increasing also the skills required for its use. On the other hand the medical science progress makes the “time” factor crucially relevant to diagnose lethal pathology and provides solutions at the early stages of its development (i.e., cancer; Grady 1992). In other words, *ceteris paribus*, an increase in the service quality, at least in terms of adoption of technology, can hold an increase in risk of being suited and in expansion of the object of compensatory claims (For instance, a 2004 decision of the Italian Supreme Court established the right of compensation for iatrogenic *loss of chances* as a juridical independent category. Hence it is possible to file suit both for iatrogenic injury and iatrogenic loss of chances). On this respect a crucial role can be played by liability rules, which can or cannot favor the decision of adopting new technology.

The second strand of empirical literature is not always unambiguous as well and mainly concerns the efficacy of the policies adopted to decrease MM pressure. Decrease the pressure in this context means affecting the probability to be the target of a claim (the physician/hospital), the probability to compensate a claim (insurers), and the probability to get compensation (patient). The main target of these policies is to relieve healthcare practitioners and insurance companies from MM pressure so to decrease problems such as defensive medicine or the availability and affordability of insurance coverage. These goals should be pursued while the quality of the healthcare system is preserved or, at best,

enhanced. The policies at stake are twofold: (1) reforms in the realm of tort law, not designed specifically to tackle MM problems, but that can directly or indirectly affect the behavior of the parties struggling with MM problems, and (2) reforms affecting the organization of the MM insurance market.

A first group of policies/reforms related to tort law has been the most studied in the USA from an empirical perspective. These policies have been distinguished in *direct* (i.e., caps on damage compensations) and *indirect* (i.e., pretrial screening panels) (Kachalia and Mello 2011; Kessler 2011). Although the evidence on the final impact of these policies on both liability and care-related measures is mixed, direct reforms seem to be associated to a stronger effect and in particular caps on damages are regarded among the most effective adoptable measures to decrease MM pressure².

Besides these two groups, tort reforms might include also the shift from negligence to no-fault liability and the adoption of form of enterprise liability. These reforms, differently from the previous, have often been adopted with specific reference to MM, as in the case of the UK (i.e., enterprise liability of hospitals; Fenn et al. 2004), Virginia, and Florida (i.e., no-fault system for severe birth-related neurological damages), as well as the Scandinavian countries (i.e., no-fault liability system for every medical injury). In the European cases the change in the liability regime was accompanied by a change in the MM insurance structure. It coincided with a change from a private/commercial to a public-taxpayers'-paid insurance coverage. The two shifts not always coincided. For example, Denmark adopted left the fault liability system for a no-fault system in 1992, but only from 2004

²However, the empirical results are ambiguous, and they depend (1) on the caps' target, as punitive damages, rather than economic or noneconomic damages, and (2) on the period of caps' introduction, the reforms implemented in the 1970s, in the 1980s, or in the 1990s. For a review see Kachalia and Mello (2011). Many European countries adopt schedules of noneconomic damages rather than caps, as in the case addressed by Bertoli and Grembi (2013)

the insurance system became completely public (also for private providers until 2013). So far, it has been difficult to empirically disentangle the effect of the change in the liability regime from the change in the insurance regime, so the attention has been focused especially on some elements of the latter, as in the English case (Fenn et al. 2007). The problems related to systems of public insurance as the case of the English *Clinical Negligence Scheme for Trusts* under a fault system or, for instance, of the Swedish *Patient Compensation Insurance* under a no-fault system are that public insurance can trigger common pool of risks more than private insurance. This means that often other institutional elements are requested to play a crucial role when adopting a public coverage, as for instance a proper monitoring mechanism on the flow of MM claims by a proper authority (Towse and Danzon 1999; Amaral-Garcia and Grembi (2014)).

A sound evaluation of the effects of a shift from negligence to strict liability has not been produced yet, and therefore, the main references are often translated by the experience of car accidents. Strict liability would allow for more liquidated claims, an average level of compensation lower than under alternative regimes, and a higher incidence of fatal accidents. However, given the peculiarities of the healthcare context, there are no strong arguments to infer that we should always expect the same results.

Changes at the fault regimes of MM remain one of the most debated issues lately. For instance, a recent document of the English Department of Health released on February 2014 (Department of Health UK 2014) addresses the concerns that the liability system did not foster medical innovation. Empirical analyses, which can help to address this and the use of additional tools to incentive efficient levels of precaution given specific institutional settings, are fundamental. Gathering and critically analyzing data on medical error remains priority one for many administrations (As underlined in the General Accounting Office (GAO) (USA) reports (GAO-04-128 T). The GAO has addressed several times the Congress to take initiatives in order to collect reliable data from the States regarding malpractice trends and effects).

Mercantilism

Günther Chaloupek

Austrian Chamber of Labour, Vienna, Austria

Definition

Mercantilism is a system of economic policy and a corpus of economic doctrines which developed

side by side from the sixteenth to the eighteenth century. The main goal was to increase a nation’s wealth and power by imposing government regulation to promote the nation’s commercial interests by maximizing exports and limiting imports.

Mercantilism, Colbertism, Cameralism

Mercantilism is a system of economic policy and a corpus of economic doctrines which developed side by side from the sixteenth to the eighteenth century. As a theory, mercantilism marks the decisive step in the emancipation of thinking about economic phenomena from scholastic theology to political economy and economics as a social science of its own. With respect to economic policy, mercantilism took a variety of different forms according to the different political, economic, and social conditions prevailing in European states during the early modern period. As a consequence, there are national variants of mercantilist economic literature focusing on different aspects of the economic process.

In a more general perspective of history of ideas, mercantilism as a body of theoretical doctrines as well as a system of economic policy is part of the emergence of a rationalist worldview with its understanding of natural phenomena in terms of cause and effect, instead of purpose inherent in the substance of things. Central to the new worldview is the concept of law as a force independent of human intention applicable to external physical nature and to human nature. In the spirit of the Baconian sentence *scientia est potentia*, knowledge of such laws brings with it the power to influence the course of events according to desired goals.

The early modern period was the time when nation states took shape on the European continent and in England. It was in this context in which the new political and economic doctrines acquired practical relevance. As a consequence, the focus of mercantilist authors was primarily on relations between states and on collectives within states (Pribram 1983, p. 83). That the perspective of the individual agent was only relevant in this context explains the contempt of classical and

neoclassical economics for mercantilism, whereas other schools of thought, such as the German Historical School or Keynesianism, are more prepared to acknowledge the merits of some of its doctrines.

None of the mercantilist authors has produced a compact theoretical system of the working of the economy. Rather, “the economics of mercantilism” is an *ex post* construct of history of economic theory which has identified a number of core issues and policy problem upon which the debates centered. Among those issues, the balance of trade, or, in a wider sense, the balance of payments of a nation is the most important one. But it would be wrong to identify the emphasis on achieving an export surplus with the opinion that national wealth amounts to nothing else than the accumulation of treasure, as was and still is often suggested. Rather, an improvement of the balance of payments was in various ways seen as a policy strategy to develop a country’s economic potential and thereby enhance its power in the context of rivalry among European nations. The relevance of specific ramifications of the external balance issue, such as import restrictions, export promotions, creation of legal monopolies, acquisition of colonies, exchange controls, varied according to the different circumstances under which individual nations sought to establish themselves in the competition of European powers. The key role for economic development which is assigned to trade extends beyond external to domestic trade and the means of its promotion. Increasing awareness of interdependence of a multitude of policy instruments lead to the formulation of policy concepts with the claim to regulate the economy as a whole (Colbertism). Given the prevalence of policy aspects in mercantilist literature, for some historians of economic theory the main relevance of mercantilism consisted in providing a political doctrine for formation of national states through the replacement of the local and regional government by the central government (Schmoller 1883) or as a system of power politics (Heckscher 1935). In contrast, Schumpeter (1954) carefully elaborated the substantial contributions of mercantilist authors to theoretical economic analysis.

If mercantilist economics had an early start in England, this can be attributed to the fact that the government had reached a comparatively high degree of centralization at the beginning of the Modern Age. In addition, consolidation of the central government coincided with the buildup of a colonial empire with its rapidly expanding trade. Conflicting interests of commercial capital are reflected in books and pamphlets whose authors often “clothed their views in the garb of a policy designed to strengthen the nation” (Roll 1942, p. 58f). Gerard de Malynes (ca. 1555–1643) warned against the loss of precious metal due to the fall of the exchange rate below silver parity which he attributed to the lack of foreign exchange controls and to the privilege of the East India Company for limited export of bullion. This focus on exchange rate was contradicted by Edward Misselden (ca. 1608–1654) who introduced the concept of balance of payments which should be seen as true indicator whether trade was beneficial for a country. A surplus should be achieved through promotion of exports and discouragement of imports, especially imports of luxuries. Interests of commercial capital found their “fullest expression” (Roll, p. 75) in the work of Thomas Mun (1571–1641). Building upon Misselden’s balance of payments theory, Mun argued that the export surplus augmented the capital (“stock”) that could be invested in trade and production and thus enhanced wealth and power of the nation. The debate between Josiah Childs (1630–1699) and Sir Dudley North (1641–1691) focused on the interest rate as a possible cause for the depression which hit England during the period of naval warfare against the Netherlands. Childs argued that the high interest rates which English merchants had to pay in comparison with Dutch competitors were responsible for depression and called for limits to be enforced by the state. North reversed the argument by saying that it was an increase in the volume of trade which would lead to an increase of the quantity of money and thus lower the rate of interest. If North proposed to do away with measures of trade protection and prohibition for that purpose, this foreshadows the end of mercantilist thinking in England. Of the important

contributions of Sir William Petty (1623–1687), mention should be made of his *Political Arithmetick* in which he advocated the use of *number, weight, and measure* in debates about economic issues – an early example of quantitative empiricist method in the attempt to establish laws of nature. English mercantilist authors extensively reflected also on prices and wages, taxation, population, etc., in the context of their respective causes. First attempts to assemble these elements of economic analysis into a coherent system from a mercantilist perspective, i.e., from the perspective of the state, were undertaken by Richard Cantillon in his *Essai sur la nature du commerce en general* (1755, originally written in English) and by Sir James Steuart in his *Principles of Political Economy* (1767).

If the **Netherlands** are often cited as model by English mercantilists, this is due the close identification of the country's government with the interest of the merchant class. While the political influence of the landed aristocracy in politics was still strong in England, in the seventeenth century Holland is the merchant state *par excellence*. The interests of Dutch merchants were best served by free trade for which the legal sciences (Hugo Grotius) provided the best arguments.

Following a path different from England in its formation of a national state, in **France** political and administrative power had been concentrated the hands of the king ruling as absolute monarch. French mercantilism was above all a comprehensive system of administration which sought to develop the economic powers of the country through “retablissement des manufactures,” advocated by Bartéhelemy Laffemas (1545–ca. 1612) who served as *controleur* under King Henri IV (Sommer 1920/1925, p. 29). A similar approach was pursued by Antoine de Monchrétien in his *Traicté de l'oeconomie politique* (1615) in which this term appears for the first time. French mercantilism was fully developed in practice, much less in theory, during the reign of Louis XIV by his finance minister Jean Baptiste Colbert (1619–1683). Under Colbert, population policy was adjusted to the aims of power policy, external trade was conducted as a kind of warfare against England and the Netherlands, the acquisition of

precious metal was proclaimed as the main objective of external trade, all measures of commercial policy were ruled by the endeavor to promote exports and prevent imports of final products (Pribram 1983, p. 51). “Colbertism” came to be used as synonym for mercantilism. It was the model for the “cameralist” system established in Austria in the eighteenth century.

In the territorial states of the **German Empire**, mercantilist practice and theory appears in different forms. In Prussia and in the Austrian monarchy mercantilist policies were deliberately used to create a unified internal market, thereby also strengthening political control of the central government over the heterogeneous provinces. Among the cameralist authors who offered their advice to the Habsburg Emperors, Johann Joachim Becher (1635–1683) made the most important theoretical contributions with his doctrine of market forms which distinguishes between monopoly, “polypolium,” i.e., free competition with free access to markets, and “propolium,” by which he means various kinds of restrictive or speculative practices. Rejecting all three forms, Becher pleads for some kind of organized and supervised competition. Becher assigns a key role to commerce in the efforts to make the economy more dynamic and recommends the foundation of sectoral trading companies by the state as instrument to encourage industrial activities. Philipp Wilhelm von Hörnigk, in his book *Österreich über alles, wenn es nur will* (1684) drew up a comprehensive program to create a national economy in the Habsburg crownlands. Hörnigk's tract as well as later cameralist literature highlight the essentially defensive orientation of Austrian mercantilist policies, which aim at an improvement of the external balance through a strategy of import substitution, in contrast to offensive export promotion by Western European states. Veit Ludwig von Seckendorff (1626–1692) who served as chancellor in the small state of Sachsen-Weimar puts significantly more emphasis on general conditions of production, such as reliability of legal framework, a stable monetary system, moderate taxation, education and training, investment in infrastructure, improvement of sanitary conditions, etc., while on

the other hand he devotes much less attention than Becher to interventionist measures of promotion of trades.

Johann Heinrich Gottlob Justi (1717–1768), the most important cameralist author of the eighteenth century, came close to recommending autarky. If external commerce was beneficial, it was not a necessity. “An empire may be very powerful, wealthy and flourishing without having external commerce with other peoples; alone, never can there be a state of such a character if its manufactures and industries are not flourishing.” It is in this context where Justi developed his central concept of *Universalkommerz* for which Colbert’s system served as model: “The sovereign has to direct all trades according to the needs of the country and to the requirements of its external commerce, of the promotion and augmentation of the livelihood of its subjects, and – in brief – of the general welfare.” Earlier than in England, chairs were established at German universities for mercantilist economics under the title “cameral sciences” or “police sciences,” the first one 1727, in Halle, Prussia. German textbooks, such as Justi’s *Grundsätze der Polizeywissenschaft* (2 vols., 1756) and Joseph von Sonnenfels’ *Grundsätze der Polizey, Handlung und Finanz* (3 vols., 1765ff), are handbooks for practical policy, rather than syntheses of analytical knowledge.

Well into the twentieth century, popular perceptions of mercantilism have been shaped by Adam Smith’s attack on what he called the “commercial” or “mercantile” system for its comprehensive regulations of imports and exports which he considered undue restrictions of freedom and obstacles to augment the wealth of a nation. Meanwhile, economic history and history of economic theory have corrected Smith’s verdicts in important respects and produced a more balanced picture of the merits and errors of this early stage of economics. It is widely recognized that free trade cannot under any circumstances be considered the best strategy to foster economic development, which can be supported by well-designed, temporary state interventions. On the other hand, a strategy of export-led growth which can turn into some kind of “new mercantilism” has

remained a powerful temptation not only for newly industrializing nations, with the risk of accumulating large-scale international imbalances. It appears that important issues of mercantilist economics will remain relevant in the twenty-first century.

Merger Control

Tim Reuter

RBB Economics, Brussels, Belgium

Abstract

Merger control is at the heart of competition law institutions throughout the world. Firms, before they complete a merger or an acquisition, are required to get the transaction approved by competition authorities. The objectives of merger control, limiting the accrual of market power and protecting the welfare-generating competition forces of

the market, are well in line with economic theory. Economic theory has identified several types of effects that can arise from a merger, in particular unilateral and coordinated horizontal effects that result from an elimination of competition between firms supplying substitutable goods, and non-horizontal and conglomerate effects that result if firms are active on vertically or otherwise linked markets. We discuss the reasoning behind these effects and how they are assessed by competition authorities. We also discuss market definition as a first step in the assessment of mergers and the legal framework under which mergers are controlled.

Introduction: Objective of Merger Control and a Classification of Merger Effects

In most jurisdictions throughout the world, merger control procedures are a central element of competition law institutions. The objective of merger control is to limit the accrual of market power and to maintain the process of competition in the market in order to protect (consumer) welfare. To achieve these ends, merger control procedures must anticipate the competitive effects mergers will bring and establish enforceable rules according to which mergers are blocked or approved. In certain jurisdictions, merger control rules might have objectives other than maintaining competition, for example public interest objectives. Such objectives are however usually not considered as part of competition law in the narrower sense. We will not discuss these aspects in this note.

From an economic theory perspective, the first general theorem of welfare economics states that Pareto efficient allocations will only be achieved if firms behave as price takers, i.e., act as if their own output decisions have no influence on price or, in other words, have no market power. In comparison to such models with atomistic firms, models with imperfect competition feature losses of consumer welfare. The objectives of merger control are hence in line with a welfare

maximization objective. It is also general consensus that it is preferable to limit the accrual of market power via merger control over regulating firms not to exercise their market power once acquired (though competition laws have provisions to also limit the exercise of market power).

While an increase in market power leads to a lessening of (consumer) welfare from an economic theory viewpoint, mergers may be conducted without any effect in market power. They may even entail procompetitive effects. For example, it may be easier to generate economies of scale or scope after a merger. Mergers may also be conducted to increase productive efficiency or to merge two complementary businesses. The trade-off between allowing firms to realize efficiencies and allowing them to accrue market power has been denominated as “Williamson trade-off” after a famous paper by Williamson 1968. As such, any merger control regime that would block mergers per se would be overly interventionist. Instead, in competition law regimes throughout the world, case-by-case assessments are conducted, in order to predict the competitive effects the mergers entail.

From an economics perspective, mergers can lead to consumer harm in several ways. First, harm can arise from a lessening of competition if firms merge that are active on the same market, i.e., supply substitutable products. Such harm is labelled a horizontal effect. Two types of horizontal effects are distinguished: The first type arises if the merged entity has an incentive to increase prices as a result of a reduction of direct competitive pressure by the removal of a competitor. This is called a “unilateral effect.” The second type arises if the merger facilitates for the remaining firms in the market to coordinate on some anti-competitive behavior. This is called a “coordinated effect.”

A second category of potential harm is called vertical effects, i.e., effects that arise if the firms are active on related segments of the same supply chain. Vertical effects typically require that some competitor is foreclosed from accessing either inputs or customers. Finally, conglomerate effects can arise. Under conglomerate effects, merging firms neither supply competing goods nor are

they vertically linked. Harm can arise, because the merged firm can leverage its broader scope (for instance by bundling complementary goods). As a rule of thumb, horizontal effects are the most frequent concern. Vertical and conglomerate mergers are less likely to entail anticompetitive effects and even often give rise to procompetitive effects.

The Legal Framework of Merger Control

Before discussing the substantive economic assessment of mergers, based on which it will be decided whether a proposed merger is prohibited or not, we describe in this section certain procedural aspects of merger control. We focus on aspects that are common to most jurisdictions throughout the world.

First of all, usually not all mergers are assessed by competition authorities. Depending on the jurisdiction, usually some notification thresholds exist, below which mergers do not need to be cleared. These can be traction volume based (for example, in the USA, generally transactions in excess of 78.2 million USD are notifiable) or turnover based (under European Union law, mergers are notifiable if the combined worldwide turnover exceeds 5,000 million EUR or if the EU turnover of at least one concerned entity exceeds 100 million EUR). In most countries, notification means that a transaction must be approved before it is completed (where gun-jumping fines may be applied).

Regarding the scope of activities undertaken, the word merger control might suggest a too narrow definition of what it covers. In reality, in some jurisdictions, also concentrations short of a merger or an acquisition fall under merger control rules. For example, in the European Union, joint ventures have to be notified under certain conditions, and in some jurisdictions, also minority shareholding acquisitions have to be notified.

The role of authorities and courts can also differ fundamentally between jurisdictions. For example, under the European Union Merger Regulation, the European Commission can challenge mergers directly. Courts play only a role should

any party (including third party complainants) appeal the European Commission's decision. In the USA in contrast, mergers are investigated by the Department of Justice or the Federal Trade Commission. Should they decide to challenge a merger however, they have to seek an injunction in front of a court. Either way, usually precise time tables govern the merger control procedures.

Finally, the choice of competition authorities (or courts where applicable) is not limited to a choice between approving a merger and blocking it. Firms can also propose to remedy the concerns raised by competition authorities. These can be structural, i.e., the merging parties agree to divest certain activities (where the divestment transaction may be itself subject to merger control) or behavioral, i.e., the merging parties commit themselves to some postmerger behavior as agreed with the competition authorities.

The Substantive Assessments of Mergers

As discussed in the Introduction, the objective of merger control comes from the notion that restricting the accrual of market power enhances welfare. To implement this into enforceable rules, different legal tests have been established according to which mergers can be blocked. While traditionally, in many jurisdictions, the legal test for prohibiting a merger was whether it would establish or strengthen a dominant position; nowadays most jurisdictions have adopted a more nuanced test.

For example, according to the European Union Merger Regulation enforced by the European Commission (and most member states have similar rules), a merger is to be prohibited if it causes a *significant impediment of effective competition* (the so-called SIEC test), in particular if it gives rise to a dominant position (until 2004, the creation or strengthening of a dominant position was the sole reason for a prohibition under European merger control). Similar, in the USA and the UK, a merger is to be prohibited if it gives rise to a *substantial lessening of competition* (the so-called SLC test). While the SIEC test explicitly mentions the dominance criterion as a particular example

under which mergers can be blocked, the SIEC and SLC tests are generally considered to be similar and remaining differences for practical purposes are nuanced.

In the following, we describe how competition authorities economically assess and decide whether a proposed merger is to be cleared or blocked (and whether remedies might be appropriate) according to the SIEC or SLC test. This description is based on guidelines that various competition authorities have published to provide guidance on their assessment of mergers. In particular, the European Commission published a “Commission notice on the definition of the Relevant Market for the purposes of Community competition law” (1997), “Guidelines on the assessment of horizontal mergers” (2004), and “Guidelines on the assessment of non-horizontal mergers” (2008), while the US Department of Justice published “Horizontal Merger Guidelines” (2010) and “Non-horizontal merger guidelines” (1997).

A first step in the assessment of likely effects is the definition of the relevant market. Then, if necessary, horizontal and nonhorizontal effects are assessed. We discuss each of these steps in turn.

Market Definition

The first step of the assessment of mergers under both the SIEC and the SLC test is the definition of the relevant market. The objective of defining the relevant market is to identify the competitive constraints firms face and to provide a framework for the competitive assessment. In particular, defining the market allows the measurement of market shares and other concentration-based statistics.

The definition of a relevant market comprises the combination of both a product market definition and a geographic market definition. With respect to the product market definition, a given product market is constituted by all products that are interchangeable or substitutable by consumers. The substitutability is to consider all product characteristics, prices, and the intended use of the products. With respect to the geographic market definition, the market comprises all areas

in which the conditions for supply and demand for the given services are homogenous and can be distinguished from other areas in which conditions of competition are sufficiently different.

In practice, to assess the relevant market definition, the Hypothetical Monopolies Test (“HMT”) is implemented. The HMT is a sequential test that starts with the narrowest possible candidate market and asks whether it would be profitable for a hypothetical monopolist in that market to implement a small but significant non-transitory increase in price (“SSNIP”). If so, it is worth monopolizing the market, i.e., a monopolist in this market does not face significant competition from outside this market and the relevant market is found. If it is not profitable to increase prices, the hypothetical monopolist faces some competition from outside the market. The candidate market definition is discarded. As next sequential step then, the candidate market definition is widened and the SSNIP question is reapplied assuming a hypothetical monopolist for the wider market. The process is reiterated until a market is wide enough such that the price increase is profitable. For this market, the hypothetical monopolist faces no significant competition from outside the market.

The HMT can be implemented using several empirical techniques to answer the question whether a price increase is profitable for the hypothetical monopolist, for example critical loss analysis, demand estimation, analysis of geographic sales patterns, analysis of price levels and price correlation, and stationarity analysis (see Gore et al. 2013 for a description of these techniques).

Finally, it should be noted that certain commentators have argued that in some cases, market definition may not be a necessary step and that economic effects can be directly assessed (see Kaplow 2010). This notion seems to be better received in some jurisdictions (in particular in the USA and the UK) than in others.

Horizontal Effects

Horizontal effects may arise under mergers of firms that supply substitutable goods, i.e., firms

that are competing directly with one another. Two types of horizontal effects are distinguished. First, a merger may eliminate direct competition between the merging firms (called a “unilateral effect” or a “noncoordinated effect”). Second, a merger may lessen or impede competition by making coordinated behavior more likely, i.e., behavior of multiple firms that is profitable for each of them only as a result of the reactions of the other firms, i.e., (tacit or explicit) collusion (called a “coordinated effect”). We discuss unilateral and coordinated effects in turn.

Unilateral Effects

A first step in the assessment of unilateral effects is usually the calculation of market shares and other concentration measures, such as the Herfindahl concentration index (“HHI”). These measures are in particular useful evidence if products are homogeneous, if capacity can be easily expanded, and if goods are traded in a spot-market fashion. In these cases, concentration measures often constitute a presumption for the competitive effects of the merger (for instance, the European Commission presumes that there is a significant impediment of effective competition if the combined market shares of the merging parties are above 40%; in US enforcement, mergers involving an HHI increase of more than 200 points are presumed as likely to enhance market power). In some cases, competition authorities conduct price-concentration analyses, investigating whether there is an empirical relationship between the concentration in a market and its given price level.

However, concentration-based measures are in many cases only the starting point of the competitive assessment of mergers. Further elements are particularly relevant if products within the market are not homogeneous, if firms in the market face capacity constraints, or if customers procure the goods in a nonstandard way, for example, via auctions.

Concentration-based criteria are unable to inform competition authorities in a precise way about the competitive constraints firms face, in particular in markets, in which products are differentiated. For instance, if the market definition has revealed that the three products A, B, and

C are in the relevant market, and if B and C have the same market shares, the concentration-based criteria presume that B and C exert the same competitive constraint on the pricing of product A. However, consumers may actually be more willing to substitute product A with product B rather than with product C. In such a case, competition authorities investigate typically the precise substitutability between products to determine the relative importance of all products in the defined market as competitive constraints to the products of the merging firms.

For instance, the European Commission investigates the closeness of competition of goods within the relevant market. One piece of evidence for this purpose can be an analysis of diversion rates, e.g., the fraction of unit sales lost by a price increase of a certain goods that would be diverted to the sales of a second product. A high diversion ratio from a product of one of the merging firms to a product of the other merging firm is an indication of a high likelihood of an anticompetitive effect (*ceteris paribus* the market shares).

Competition authorities use a number of empirical techniques to assess the competitive constraints imposed by particular products within the relevant market, for example, diversion rates can be assessed using survey evidence, customer switching data from firms’ market intelligence databases (e.g., mobile number portability data in the case of mobile network operator mergers – see European Commission 2016), assessments of natural experiments (e.g., switching as the result of a closure of a plant – see Coate 2012), and analysis of win/loss data (see Botteman 2006). Advanced tools to estimate the constraints of particular products are upward pricing pressure tests (see Farrell and Shapiro 2010) and merger simulation models (see Budzinski and Ruhmer 2009).

Other factors that play a role in the assessment of unilateral effects are entry, capacity constraints of suppliers, countervailing or buyer power, efficiencies generated by the merger, product repositioning, failing firm defense, effects of the merger on innovation and product variety, and a loss of potential competition (e.g., one merging party planning to enter a given market where the other is already active). These factors may be

treated differently in different jurisdictions however. For example, Brouwer (2008) points out that the main difference between EU and USA merger policy lies in the greater scope for efficiency arguments in the USA.

Coordinated Effects

The notion of coordinated effects relies on the idea that a merger can make (tacit) collusion more likely to arise or can increase its effectiveness. As is well established by economic theory, collusive situations are difficult to establish for firms, because in a static setting, firms have generally an incentive to deviate from such situation by competing more aggressively. However, in a dynamic setting, collusive situations can be stable such that no firm has an incentive to deviate.

For the implementation in merger control, coordinated effects are assessed by judging whether the relevant market is generally vulnerable to coordinated conduct and whether the vulnerability increases by the merger.

For the vulnerability of the market in general, it is usually assessed (i) whether the firms in the market are likely to reach a common understanding of the terms of the coordination, (ii) whether firms can monitor whether all firms adhere to the coordination conduct, (iii) whether credible deterrent mechanisms are available that prevent firms from deviating from the coordination, and (iv) whether outside firms (competitors or customers) have ways of destabilizing the coordination.

As shown in economic theory, (tacit) collusion in dynamic settings often has many equilibria (see Friedman 1971). It is less clear which equilibrium may be a focal point and how firms coordinate on a specific tacit collusion equilibrium to play. This is reflected in the assessment of coordinative effects that firms must reach an understanding of the terms of the coordination conduct. While in some markets, for example, a market with few competitors, where competitors are symmetric, with homogenous products and that is not strongly affected by entry and innovation, reaching such an understanding may be simple. In markets which are more complex, reaching a tacit understanding is less likely. Hence, merger

control takes these market characteristics into account when assessing coordinative effects.

The ability of firms to monitor and punish deviating firms depends on market characteristics such as transparency and stability of demand conditions (i.e., to determine whether an unexpected market outcome is result of deviating behavior or result of demand fluctuation), frequency and concentration of orders (it becomes more difficult to punish if orders are lumpy), and whether firms compete in a single- or multimarket setting (as punishment can also occur on markets other than the one on which coordination takes place).

Finally, competition authorities take reactions by other firms into account, for example whether competing providers that do not take part in the coordination have the ability to increase capacity, whether third parties can enter in the market and whether customers have countervailing power that can destabilize the coordination.

For the facilitation of coordination by the merger, after all what matters in whether coordination becomes more likely or more effective by the merger, the reduction of the number of firms active can be enough if market concentration is sufficiently high. However, even if the merger does not cause a significant increase in concentration, coordinative effects can be found, for example, if one of the merging firms is found to be a 'maverick,' i.e., a firm that is known to be disruptive to the market, e.g., by pricing aggressively or by innovating regularly.

Nonhorizontal Effects

A merger can also affect market outcomes if the merging firms do not compete on the same market, but are active on different levels on the same supply chain (i.e., a vertical merger) or are active on different markets that are somehow related, for example, two markets for complement goods (i.e., a conglomerate merger).

In general, nonhorizontal mergers tend to be less likely to raise competitive concerns than horizontal mergers, because unlike the latter, they do not lead to a loss of direct competition between the merging firms. Often vertical mergers solve

inefficiencies in the supply chain and are hence procompetitive; for example, they reduce double-marginalization (i.e., lower downstream prices, because the merged entity internalizes increased upstream profits from an expansion of output if downstream prices decrease), decrease transaction cost, or reduce prices for complement goods.

However, vertical mergers may not only solve inefficiencies and lead to procompetitive effects, but can under certain circumstances have anticompetitive effects as well. Two types of such anticompetitive effects are input foreclosure and customer foreclosure. Input foreclosure relies on the notion that a firm active on a downstream market, by vertically integrating upwards, can start supplying its competitors on the downstream market on unfavorable terms only, thereby weakening downstream competition and increasing downstream prices. Customer foreclosure, on the other hand, means that a firm on an upstream market, by integrating downward, can shrink the customer base of its upstream competitors, thereby decreasing the ability of the upstream competitors to compete. In result, upstream prices may increase, whereby competition on the downstream market is hurt, leading to an increase of downstream prices.

Whether it is for the merging firms possible and profitable to foreclose competitors from accessing inputs or customers is however dependent on the specific market characteristics. For example, a downstream competitor cannot be foreclosed by a vertical merger if the merged entity does not have sufficient market power in the upstream market, because the downstream competitors can get access to the input from competing providers (at competitive terms). Similar, while input foreclosure may increase the integrated firm's profits on the downstream market, it pays a cost for the foreclosure by lost profits resulting from less sales on the upstream market. As such, the merged entity might not have an incentive to engage in foreclosure, for example, if upstream margins are high and downstream margins are low.

In a similar vein, customer foreclosure is not necessarily possible and profitable for vertically integrated firms. First of all, for customer foreclosure to be possible, the integrated firm must have a sufficient degree of market power in

the downstream market, such that competing upstream providers may actually face a significant loss of sales opportunities. Second, the loss of customers for the upstream competitors must entail that they are not able to compete any more effectively, which requires some form of economies of scale or scope for the upstream providers or that they operate at or close to minimum efficient scale. The profitability of consumer foreclosure depends on a similar trade-off as that of input foreclosure: By customer foreclosure, the integrated firm can lower competition and raise prices on the downstream market. To do so, it has however to carry additional costs on the upstream market (by eventually not procuring from the cheapest provider).

Foreclosure concerns can also matter in conglomerate mergers, i.e., for mergers in which the merging firms are active neither on the same market, nor on vertically linked markets. Similarly to vertical cases, conglomerate mergers will often entail procompetitive effects, for example, when the merging firms sell complementing goods (because they will lower prices for both goods, taking into account that a price decrease for one good will trigger an increase in demand for the complement). As well similar to vertical mergers, they can however trigger foreclosure concerns. For example, by tying or bundling two goods together, the conglomerate firm may leverage market power it holds in one market to another market to achieve above-competitive prices in that market. However, the firm will only have the possibility to leverage the power of one market to the other, if its market power in the first market is sufficiently high and if a large enough share of the consumers who buy one good also want to buy the second. The profitability of such foreclosure depends on the trade-off between losses in the market with market power (because some customers might refrain from buying this good if it is bundled to the other good) and gains in the market to which the power is leveraged.

For all types of foreclosure, competition authorities are hence comprehensively assessing market power of the integrated firm in at least one market, the cost of leveraging the market power that is entailed on the same market, and the benefit the leveraging causes on the second market.

Merger Remedies

Patrice Bougette

Department of Economics, Université

Côte d’Azur, CNRS, GREDEG,

Nice, France

Abstract

Merger remedies are used by competition agencies to prevent the harm to the competitive process that may result as a consequence of a merger. They allow for the approval of mergers that would otherwise have been prohibited, by removing the anticompetitive concerns that a given transaction may pose to competition. First, we present the typology of merger remedies generally used. Second, we analyze the link between the size of the offered remedies and the level of efficiency gains announced in a context of asymmetric information. Third, we summarize the results of several retrospective merger studies in which remedies have been used.

Competition agencies use merger remedies when a notified merger is likely to raise some competitive concerns. In this case, the merging firms may make a remedial offer, which may be accepted or rejected by the agency. In this entry, we derive examples mainly from the European Commission (hereafter “the EC”) even though most mechanisms can be found in any competition agencies worldwide.

Actually, remedies are relatively less used with respect to the total number of notified merger proposals to agencies. According to the EC’s data, less than 10% of notified mergers are eventually conditioned upon merger remedies (see the EC’s website for detailed data on the European merger control, <http://ec.europa.eu/competition/mergers/statistics.pdf>). The majority are approved without any conditions. However, these remedies may be found in large or complex merger cases. In the absence of remedies, such mergers would be rejected.

Types of Merger Remedies

Two types of remedies are commonly used by competition agencies, structural and behavioral remedies. We first detail them and then discuss the pros and cons of each in terms of implementation.

Structural remedies refer to a transfer of ownership rights. For instance, merger firms commit themselves to selling a portion of their assets to one or several buyers. The selected assets may be located in markets where the level of concentration is very high. These assets are often the merging parties' overlap. For instance, in 2016, the EC approved the acquisition of beer group SABMiller by Anheuser-Busch InBev provided that, among other commitments, the new group divested SAB's brands Peroni, Pilsner Urquell, and Grolsch (*ABI/SAB* merger case, M.7881; see the EC press release, "Mergers: Commission approves AB InBev's acquisition of SABMiller, subject to conditions," 24 May 2016).

By nature, structural remedies are difficult to reverse and may largely apply to horizontal practices. The sale of an independent activity operating in the market appears more effective than a transfer of heterogeneous assets from the two merging firms (see the European Commission (2005)'s study for a categorization of these remedies).

Behavioral remedies may be defined as constraints on the property rights of the new entity. These commitments do not affect the market structure. They include third-party access to infrastructure or technology, or the parties commit themselves to putting an end to any exclusive vertical agreements. For instance, in the context of the acquisition of Ariespace by Airbus Safran Launchers (ASL), a joint venture between Airbus and Safran, the EC had concerns that the transaction would give rise to flow of potentially sensitive information between the two companies. This would have been at the expense of rival satellite manufacturers and launch service providers. Among other behavioral remedies, the companies committed not to share information about third parties with each other (*ASL/Ariespace* merger case, M.7724; see the EC press release, "Mergers: Commission approves

acquisition of Ariespace by ASL, subject to conditions, 20 July 2016).

In general, competition agencies have a preference for structural commitments. Indeed, a behavioral remedy involves direct monitoring costs, whereas in the case of a structural remedy, once transferred, the assets no longer need special monitoring. However, in this case, it may be useful to set up a follow-up mechanism until the assets are sold. For instance, with regard to complex merger cases, an independent trustee may be appointed to monitor the smooth transfer of assets and strict compliance with time limits (see the Commission Notice on remedies acceptable under the Council Regulation (EC) No 139/2004 and under Commission Regulation (EC) No 802/2004 Official Journal C 267, 22.10.2008, p. 1–27, http://ec.europa.eu/competition/mergers/legislation/files_remedies/remedies_notice_en.pdf).

Nevertheless, the preference for a structural option may be flexible and adapted to the case context. First, the two types of remedies are not necessarily exclusive, behavioral commitments may be useful to a structural solution (see, e.g., the EC *Orange/Jazztel* merger case, M.7421, 19 May 2015). Then, in some cases, perhaps no competitor is interested in the proposed assets, in which case the agency turns to a behavioral commitment. In addition, in highly changing market circumstances, nonstructural remedies may constitute a more flexible and a revisable solution (Motta et al. 2007). Lastly, transfer of assets may facilitate collusion if they lead to a more symmetric industry structure. Compte et al. (2002) show that due to the use of remedies, coordinated effects emerged in the context of the 1992 *Nestlé–Perrier* merger case.

Efficiency Gains and Asymmetric Information

A number of theoretical models have focused on the effects of structural merger remedies. For instance, such remedies enlarge the scope for approvable mergers in the presence of merger synergies. Nonetheless, if the merger does not lead to any efficiency gains (i.e., cost synergies),

only under very restrictive conditions, reallocation of assets through structural remedies may satisfy the criterion of consumer surplus (Vergé 2010).

With regard to the nature of the *ex ante* merger control, asymmetric information problems arise between the merging firms and the competition agencies. Firms know precisely the level of their own efficiency gains expected, while the competition agency may doubt the real level of expected synergies (adverse selection). The merger remedies may be used to signal the true type of efficiency gains (see, e.g., Dertwinkel-Kalt and Wey (2016)).

The strategic trade-off for the merging firms is the following. On one hand, the greater the synergies of a proposed merger, the more companies may value their assets, and therefore are reluctant to propose significant commitments. Thus, theoretically, efficiency gains reduce the size of the proposed commitments (Cosnita and Tropicano 2009; Bougette 2010).

On the other hand, this argument does not take into account the temporal dimension of the trade-off. The EC's investigations are costly for merging firms. In this sense, firms may judge that it is preferable to divest more assets ("overfixing" strategy) than what exactly would suffice to resolve the competition concern, in order to avoid a long, and therefore, costly control procedure. Thus, in spite of the high level of synergies generated, the merging companies may then be inclined to give up on strong commitments simply because they are delay averse.

Cosnita-Langlais and Tropicano (2012) analyze the link between the efficiency defense and the use of remedies. They model the quality of information held by the competition agency and show that it may be best for the agency to prohibit the efficiency defense when the information quality is poor.

Merger Remedies Retrospective Studies

With regard to empirical applications dedicated to remedies, several levels of study in the literature may be specified.

First, empirical analysis has focused on specific merger cases. These studies aim to assess the effectiveness of the decision made by competition agencies. Structural remedies may have been used and could be evaluated as such. In most cases, a difference-in-differences approach is adopted. The chosen econometric method allows for estimating a counterfactual, namely, what would have occurred in the absence of the studied merger, or in this case, in the absence of remedies. For example, Tenn and Yun (2011) show that the structural remedies used in the 2006 *J&J-Pfizer* merger resulted in the return of the premerger situation.

Second, another approach to evaluating selected remedies is to build a database of merger decisions including the ones with remedies and to analyze the determinants of these remedies. Several studies on the EC's data have been released in this perspective (see, e.g., Bougette and Turolla (2008)). Some of them have studied the merger control process in general, while others focus exclusively on the remedial decisions. For instance, Duso et al. (2011) show that remedies may be more effective when anti-competitive concerns are not too harmful and when applied to the first rather than the second investigation phase.

Time actually plays a considerable role in companies' strategy to provide more or less strict merger remedies, when needed. By studying 254 cases of mergers from the EC over the period 1999–2010, Ormosi (2012) shows that companies that do not use an efficiency defense strategy are actually more likely to reach a deal relatively early. The experience of law firms hired for the case has a high impact on the probability of using efficiency defense, but only for European cabinets. Less restrictive remedies are more likely to be proposed by the parties at the outset of the proceedings.

Based on the EC's data, Garrod and Lyons (2016) also show that the probability of early settlement is increasing in delay costs of the merging parties, decreasing in the uncertainty associated with the complexity of the economic assessment, and decreasing in the case load of the EC when resources are plentiful.

Finally, studies and reports have been conducted and prepared by the agencies themselves in a self-evaluation exercise of their decisions. The most notable of these is the European Commission (2005) that pointed out a number of practical problems in terms of monitoring, divested asset selection, and potential buyers, among others.

Merit Goods

Valérie Clément¹ and Nathalie Moureau^{2,3}

Merit goods are a category of goods, introduced in the debate by Musgrave (1957), which individuals tend to under- or over-consume because their preferences are “irrational” or “defective.” This leads individuals to make suboptimal choices, which are detrimental to their well-being. Now, if they exist, merit goods must be produced by the government that must so to speak force individuals to consume the correct amount of these goods. In other words, the government must behave paternalistically.

The concept of merit goods was a precursor to the debates on paternalism within welfare economics. In particular, the interpretation of the merit goods concept through the meta-preferences approach helps in legitimizing legal intervention and achieving a more efficient regulation.

When Musgrave introduced the term “merit goods” (originally called *merit wants*), it was in an attempt to create a normative definition for government functions. Nevertheless, only three of the functions he studied in his article have gone down in history: (i) the provision of public goods (*service branch*), (ii) the redistribution of income (*distribution branch*), and (iii) economic regulation (*stabilization branch*). Yet, in this groundbreaking article, Musgrave also mentioned another category of goods which he called merit wants. He was referring to goods which are subject to “transfers in kind” (e.g., social housing) and for which the regulator’s preferences override individual choices (Musgrave 1957 p. 341).

In 1959, Musgrave returned to this concept of merit goods by explicitly linking it to the issue of consumer sovereignty. In some cases, when choices made by people on the markets do not

lead to a situation that maximizes their well-being, the regulator intervenes in order to address the limitations of individual preferences and correct people's choices in their own best interest.

It is nevertheless in his 1987 Palgrave article that Musgrave strengthened the definition he had introduced 30 years earlier. He clarified two points in particular which attracted most comments since they were first published.

Firstly, Musgrave confirms his initial theoretical claim that the justification for government intervention through merit goods is distinct from that linked to market failures and redistribution. Indeed, while links between merit goods, public goods, and externalities may have caused some confusion in his initial papers (Head 1966, 1969; Ver Eecke 2001), the Palgrave article provides clarification. In no way should merit goods be confused with public goods or externalities. Whereas in the case of public goods there is a link between consumers' willingness to pay and consumption levels, this link is broken in the case of merit goods. Furthermore, merit goods refer to situations where people's choices are detrimental to their own well-being without third parties being involved, as is the case with externalities.

Secondly, at the heart of the definition of merit goods lies the fact that if choices are detrimental to individual, it is because their current preferences are defective. Thus, choices then expressed in the market no longer equate with welfare. These *individual failures* could justify government interventions (Jones and Cullis 2002).

The reasons why choices made on the market may lead to a suboptimal situation have been the subject of extensive debate. In the article he wrote for the Palgrave Dictionary, Musgrave takes the view that situations in which people voluntarily delegate their choice to a more informed party, in a principal agent relationship, do not relate to merit goods. However, in his early works, he did not take this stance and had in fact used education as a prime example of merit goods. Indeed, at first he considered that the reason why education was compulsory was because people were not able to forecast the profit they would earn of such an investment. He nevertheless changed his mind, stating that it was simply an information issue

encountered by the individual which justified a delegation of choice to another better informed party (For sure, one must admit that the government is better informed; that is not at all accepted in the economic literature.) (Musgrave 1987; West and McKee 1983). Defining the concept of merit goods is rather about highlighting the inconsistency of the preference standard in order to form judgements on individual well-being. Hence, it seems that even when full information is available, wrong choices can be made and lead to a suboptimal situation for the individual.

By definition, merit goods infringe consumer sovereignty and for this reason were put aside the standard welfare economics framework as the golden standard for paternalism (McLure 1968). However, there have been attempts to model merit goods in the context of welfare economics (Pazner 1972; Roskamp 1975; Wenzel and Wiegard 1981; Salanié and Treich 2009). These attempts perhaps reflect the need to justify an extremely widespread regulatory practice. For example, OECD data shows that two-thirds of European government bodies expenditure are somehow justified in terms of merit goods (Fiorito and Kollintzas 2004) and cannot be explained by standard market failure arguments.

If current short-term preferences are disqualified, the question arises of how "authentic" preference could be defined and what it stands for. The theoretical issue underlying this question lies in the possibility of articulating merit goods with the classical liberal principle of normative individualism. Musgrave did not evade the issue. In some of his papers, he noted that there is an elite who is in a position to know people's "true preferences" or "authentic preferences" (Musgrave 1969); in other papers, he refers to collective norms or "community preferences" (Musgrave 1987).

Another way to justify the concept of merit good in the economic framework, which seems more in line with the theoretical issue, involved expanding the area of individual preferences beyond market preferences, displayed through the willingness to pay and choice, by introducing the notions of "multiple-selves" and "meta-preference." The economic agent is then defined

by a collection of different and independent personalities (Harsanyi 1955; Elster 1979; Etzioni 1986), each of which leads to a separate classification of available options. The individual is no longer a unified person and may struggle to control his/her behavior (Schelling 1984). Equally, the individual may have the ability to assess and reflect on his/her own tastes and preferences that are expressed through second-order preferences or meta-preferences (Frankfurt 1971; Jeffrey 1974; Sen 1977; Hirschman 1984; George 1998). These help reflect the individual's dissatisfaction with a choice that he/she nevertheless made. The regulator then appears as a mediator between preferences displayed on the market on the one hand and reflexive preferences on the other, this mediation being then carried out under merit goods (Brennan and Lomasky 1983).

Incorporating into the analysis this idea of the existence of several ranges of preferences enables decisions made by policymakers, legislators, and judges to be perceived as an expression of second-order or meta-preferences, which, in turn, allows for the regulation implemented under merit goods to lead to higher efficiency than that implemented by the market, while respecting the individualistic foundations of collective choice. In this sense, the interpretation of Musgrave's concept through reflexive preferences is particularly relevant when analyzing economic policies and regulation policies within a law and economics approach. As noted by Kirchgässner (2017), this ties in with an important tradition in political philosophy which, from Buchanan and Tullock (1962) to Rawls (1971), combines the choice of a constitution or of the general principles on which society is organized with higher-order preferences.

With the developments of libertarian paternalism (Sunstein and Thaler 2003), the question of the role played by merit goods in the economic framework remains topical. By exploring faulty reasoning and rationality defaults, behavioral economics actually deepen the empirical content of Musgrave merit goods' rationale. Nevertheless, this strand of literature quite surprisingly did not refer to the concept of merit good in its developments of a new framework for the state regulation. Obviously, behavioral economists argue against

merit goods' intervention as it represents hard paternalism restricting individual choices through prohibition or taxation. Behavioral economists favor nudge practices, where the regulator helps people to make the best choice through a change in the frame or in the environment of choices (Thaler and Sunstein 2008). In any case, there should not be any restriction of the available options provided through the market allocation.

Then, behavioral economics did not pay heed to the contribution of the merit goods' argument to the normative justification for the government intervention. In this respect, the continuity with the pioneering concept of Musgrave is certainly to be found in the role and definition devoted to the merit goods in law and economics following Calabresi (2016). Calabresi complements and extends the definition of Musgrave adding two reasons why merit goods should not be (and actually are not) allocated through markets: the refusal of the "commodification" and pricing of certain goods and the refusal of an allocation based on people's willingness to pay given the vast inequalities in wealth distribution in our societies.

In the first category, people object to the use of monetary evaluation and measurement for being conducive toward unacceptable trade-offs, for example, trade-offs implying life or safety and money. The second category of merit goods following Calabresi includes those goods whose measurement in monetary term is no longer objectionable, but people oppose the use of the pure market mechanisms because the allocation thus depends on the prevailing unequal distribution of wealth; examples are military service or the right to obtain body parts (blood, kidney, etc.) or the right to a basic education. Taking seriously people's actual preferences embedded in these two merit goods categories allows the society to avoid "indirect external moral costs," Calabresi argues, that arise from the denial of people's objection to commodification and to the neglecting of the distributional consequences of the pure market allocation. Hence the allocation of merit goods should rest on hybrid mechanisms involving either modified market or modified command schemes if people preferences for merit goods are taken into account. Tort laws

provide a prominent example of such hybrid mechanisms in the case of objection to commodification that lead to lessen the externalities created by merit goods, that is, “moral costs” people would bear were the merit goods (life and safety) priced directly through the market, Calabresi points out.

Merit goods lie at the heart of law and economics as Calabresi conceived it, first of all because the inclusion of people’s preferences about commodification and equality enables regulation policies to be efficient in the sense that third-party moral costs are fully integrated and lastly because the thorough study of the law and the legal institutions should serve to identify merit goods and to elicit people’s preferences about merit goods. This renewal of the merit goods’ argument confirms the initial statement of Musgrave that merit goods were a category of goods that called for the expansion of the standard economic model.

Mises, Ludwig von, Fig. 1 Ludwig von Mises

Abstract

Ludwig Heinrich Edler von Mises (September 29, 1881, in Lemberg – October 10, 1973, in New York City) was a classical liberal philosopher, sociologist, and one of the most influential adherents to the Austrian school of economics. He made major contributions to the epistemology of the social sciences and to many areas of general economics, especially the fields of value theory, monetary theory, and business cycle theory. In his habilitation thesis of 1912, *The Theory of Money and Credit*, he laid down the foundations of what would later become Austrian business cycle theory. The whole body of Misesian economics which is based on praxeology, the rational investigation of human decision making, is comprised in his 1949 *Human Action: A Treatise on Economics*. Among his disciples were such noteworthy economists as Friedrich August von Hayek (1899–1992) and Murray N. Rothbard (1926–1995).

Life, Work, and Influence of Ludwig von Mises

Life, Family, and Personal Background

Ludwig von Mises (Fig. 1), son of Arthur Edler von Mises and Adele Landau, was born in the city of Lemberg, Galicia, in the former

Austro-Hungarian Empire (today Lviv, Ukraine) on September 29, 1881. He is the older brother of the famous Harvard mathematician Richard Martin von Mises (1883–1953). His youngest brother Karl died of scarlet fever at the age of 12 in 1903.

In 1881 Emperor Franz Joseph granted Ludwig's great grandfather Meyer Rachmiel Mises a patent of nobility and the right for him and his lawful offspring to bear the honorific title "Edler" (Hülsmann 2007, p. 15). Ludwig then was the first member of his family to be born a nobleman. The whole Mises family was heavily involved in the construction and financing of Galician railways after the 1840s. So it came to pass that Ludwig's father was a construction engineer for the Czernowitz railway company in Lemberg before moving to Vienna no later than 1891 (Hülsmann 2007, p. 21).

Ludwig entered the *Akademische Gymnasium* of Vienna in 1892. There, he was given an education stressing among other things the classical languages, Latin and ancient Greek. Reading Virgil, he found a verse that he chose to be his motto for life: "Tu ne cede malis sed contra audentior ito" (translated: Do not give in to evil, but proceed ever more boldly against it) (Mises 2009, p. 55). Much later he would point out the importance of the classical literature, and in particular of the ancient Greeks, for the emergence of liberal social philosophy in *The Anti-Capitalistic Mentality*

(Mises 1956; Hülsmann 2007, p. 34). After having completed the Gymnasium in May 1900, when his major interests were in politics and history, he enrolled in the Department of Law and Government Science at the University of Vienna.

Initially, Mises studied under the Marxist sociologist and economist Carl Grünberg (1861–1940) who was an adherent of the German historical school. At the age of only 20, Mises published his first scholarly work in one of Grünberg's books on the peasants' liberation and agrarian reforms in the Bukovina (Hülsmann 2007, p. 68). He graduated with the first *Staatsexamen* in 1902 in history of law from the University of Vienna. In 1906, after completion of the military service, he passed the second and third *Staatsexamina* in law and government science. Thereafter, he was awarded a doctorate degree, *doctor juris utriusque*, from the same university by passing his juridical, political science, and general law exams.

Mises in the course of his studies shifted gradually away from the influence of historicism which was at the time the predominant method in the social sciences in the German-speaking world. Highly influenced by economists Carl Menger (1840–1921) and his follower Eugen Böhm von Bawerk (1851–1914), he published his habilitation thesis in 1912 under the title *Theorie des Geldes und der Umlaufsmittel* (translated in 1934 as *The Theory of Money and Credit*). In fact, it was Menger's *Grundsätze der Volkswirtschaftslehre* (*Principles of economics*, Menger 1871) and Böhm-Bawerk's *Kapital und Kapitalzins* (*Capital and Interest*, von Böhm-Bawerk 1890) originally published in 1884, two foundational works of the Austrian school of economics, that had a tremendous impact on Mises's thinking. Mises wrote in his *Memoirs* that it was through Menger's book that he became an economist (Mises 2009, p. 25). After his habilitation, he worked as a civil servant for the Austrian chamber of commerce and became a *Privatdozent*, an unsalaried lecturer, at the University of Vienna – the highest academic rank he would ever achieve in his native Austria.

During the First World War, Mises served as an artillery officer in the Austro-Hungarian army and

spent several months at the front. It was only in December 1917 that he was ordered to join the department of war economy in the War Ministry of Vienna. He resumed his teaching activities at the University in the spring of 1918. Among his students at that time was Richard von Strigl (1891–1942) who became an important Austrian economist of the interwar period. In 1919, he finished a manuscript under the working title *Imperialismus* which would contain his analysis of the causes of the Great War and the political challenges for postwar Europe as well as his personal war experiences. The book was eventually published under the title *Nation, Staat und Wirtschaft* (translated in 1983 as *Nation, State and Economy*, von Mises 1919). This book, although less well known today, established Mises as the foremost champion of classical liberalism in the German-speaking world and eventually in all of Europe (Hülsmann 2007, p. 300).

Mises made a new personal acquaintance with the famous Max Weber (1864–1920), who came to teach at the University of Vienna in September of 1917. Their professional relationship was characterized by mutual respect and admiration. Weber had a remarkable impact on Mises's writings on the methodological and epistemological problems of the social sciences in the 1920s. On the other hand, Weber praised Mises's monetary theory as “the most acceptable” of the time (Hülsmann 2007, p. 288).

Only a few years later, in 1922, Mises published “the most devastating analysis of socialism yet penned” (Hazlitt 1956, p. 35), *Die Gemeinwirtschaft* (translated in 1936 as *Socialism* (von Mises 1951), a book in which he gives a detailed and thorough explanation of the problem of economic calculation under socialism. In 1927, his *Liberalismus* (translated in 1962 as *Liberalism* (von Mises 1985) was first published). Two years later, *Kritik des Interventionismus* (translated in 1977 as *A Critique of Interventionism*, von Mises 1996) appeared, an anthology of articles he wrote in the early 1920s.

Throughout the 1920s until 1934, Mises held a weekly private seminar in his office at the chamber of commerce to which students and scholars not only from Vienna but from all over Europe

and the whole world were attracted. Among the numerous participants were Austrian economist Gottfried Haberler (1900–1995), Frenchman Francois Perroux (1903–1987), American economist Frank Knight (1885–1972), and even four Japanese economists (Itschitani, Midutani, Otaka, Takemura) (Hülsmann 2007, p. 674). However, as one of the best-known students and colleagues of Mises, one has to mention Friedrich August von Hayek who attended the seminar on a regular basis. Hayek became the director of the *Austrian Institute for Business Cycle Research* that Mises had established (Hülsmann 2007, p. 454). Later, Hayek would take a position at the *London School of Economics* which was an important step in his academic career.

The political developments made life in Vienna increasingly unpleasant for Mises. Being of Jewish descent and an ardent critic of socialism, he had to flee Vienna in 1938 after occupation and annexation of Austria by the German national socialists. With great foresight he had already accepted a position at the Geneva-based *Institut de Hautes Études Internationales* (Graduate Institute of International Studies) in 1934, where he became visiting professor. There, under the company of William E. Rappard (1883–1958) and Paul Mantoux (1877–1956) who led the school together for about 20 years, he had some of the most productive and fruitful years of his scholarly career, culminating in the publication of his opus magnum *Nationalökonomie* in 1940. In 1938, he would marry his longtime companion Margit Serény in Geneva.

As history moved on, Geneva as well seemed no longer to be a safe place for Mises and his wife, due to the rising threat of national socialism and ultimately the outbreak of World War II. Mises was high on the list of wanted men. In March 1938, unidentified men broke into Mises's apartment in Vienna. A few days later, the Gestapo confiscated his books, correspondences, personal records, as well as other belongings. At the end of the war, the Red Army found his files in a train in Bohemia. They were brought to a secret archive in Moscow, where they would be rediscovered in 1991, 18 years after his death (Ebeling 1997). Mises never saw his documents

again. He thought that they had been destroyed during the war.

Ludwig and Margit von Mises decided to flee Europe. After a long and arduous trip, they arrived at the docks of New York City on the third of August, 1940. At almost 60 years of age, Mises had to start a new life. He quickly sought contact with potential supporters. His brother was already professor at Harvard University. Henry Hazlitt (1894–1993), journalist at the *New York Times* and a great admirer of Mises, turned out to be very helpful. With the financial support of the *William Volker Fund*, he arranged a visiting professorship for Mises at *New York University* (NYU). Mises would remain a visiting professor for more than 20 years until he retired in the Spring of 1969, as the oldest active professor in the United States (Rothbard 1988, p. 44). His salary during that period would always be paid from private funds.

Mises set up a seminar at NYU in the spirit of his Vienna private seminar, where he gathered a diverse group of journalists, businessmen, scholars, and young university and even high school students. Hans Sennholz (1922–2007) and Louis Spadaro (1913–2008) were his first doctoral students in the United States. Other seminar members were William Peterson (1921–2012), George Reisman (born 1937), his classmate Ralph Raico (born 1936), Israel Kirzner (born 1930), and most notably Murray N. Rothbard. According to his wife, Mises encouraged all of his students to pursue scholarly work, hopeful that one of them might develop into a second Hayek (Mises 1976, p. 135). He might have found his “second Hayek” in Rothbard, although both Hayek and Rothbard developed Misesian ideas in quite different directions.

Mises's first books written in English appeared in 1944, *Omnipotent Government* (von Mises 1944a) and *Bureaucracy* (von Mises 1944b), both published by Yale University Press. *Human Action*, the extended English edition of his opus magnum *Nationalökonomie*, was published in 1949. It contains the culmination of Misesian economic theory. Among several other books and numerous articles, he published his last great work in 1957, *Theory and History* (von Mises

1957), a philosophical treatise that builds a bridge between economic theory and human history and explains the true relation between those two disciplines (Rothbard 1988, p. 110). Having devoted his whole life to the enhancement of economic theory and the social sciences, as well as the promotion of peace and individual liberty, Ludwig von Mises died at the age of 92 on October 10, 1973, in New York City.

Work and Influence

When Ludwig von Mises entered university in 1900, the social sciences in the German-speaking world, including economics, were predominantly influenced by historicism – ideologically a forerunner of positivism. Gustav Schmoller (1838–1917), under whom Mises’s first university teacher Carl Grünberg studied, was the leading intellectual of the German historical school. Mises recognized fundamental flaws within this school of thought and the academic tendencies of his time, namely, the state orientation:

It was my intense interest in historical knowledge that enabled me to perceive readily the inadequacy of German historicism. It did not deal with scientific problems, but with the glorification and justification of Prussian policies and Prussian authoritarian government. The German universities were state institutions and the instructors were civil servants. The professors were aware of this civil-service status, that is, they saw themselves as servants of the Prussian king. (Mises 2009, p. 7, as cited in Rothbard 1988, p. 51)

Mises was interested in positive social sciences, not in the promotion of political measures by the government. He was convinced that there are absolutely and uncompromisingly, in his words “apodictically,” true statements in the realm of social sciences that are not mere tautologies or conventions – an idea that historicists and positivists would decidedly reject. Mises on the other hand rejected the relativism of the historicists. He first found such uncompromisingly true statements in Menger’s *Grundsätze der Volkswirtschaftslehre*, which is widely considered to be the foundational work of the Austrian school of economics. This book made Mises an economist and an “Austrian.” Mises, among the other Austrian economists of the second and third

generation after Menger, dwelled on this epistemological and methodological point the most vehemently. He considered economics to be an “a priori” science, rooted in the broader discipline of the rational investigation of human behavior and decision making that he would term praxeology.

The Misesian body of economic theory is derived from the undeniable fact that human beings exist and act, that is, they are consciously employing means to attain ends. One cannot argue that human beings do not act, that they do not employ means to attain ends, since such an argument would precisely be an action as described above. By acting, human beings make choices, they demonstrate preferences, and they engage in exchanges. They make value judgments – they decide for one opportunity and they forgo others, that is, they pay a price. Mises shows that all fundamental economic concepts, such as value, exchange, preferences, prices, costs, and gains, are inherent to human action:

Action is an attempt to substitute a more satisfactory state of affairs for a less satisfactory one. We call such a willfully induced alteration an exchange. A less desirable condition is bartered for a more desirable. What gratifies less is abandoned in order to attain something that pleases more. That which is abandoned is called the price paid for the attainment of the end sought. The value of the price paid is called costs. Costs are equal to the value attached to the satisfaction which one must forego in order to attain the end aimed at.

The difference between the value of the price paid (the costs incurred) and that of the goal attained is called gain or profit or net yield. Profit in this primary sense is purely subjective, it is an increase in the acting man’s happiness, it is a psychological phenomenon that can be neither measured nor weighed. There is a more and a less in the removal of uneasiness felt; but how much one satisfaction surpasses another one can only be felt; it cannot be established and determined in an objective way. A judgment of value does not measure, it arranges in a scale of degrees, it grades. It is expressive of an order of preference and sequence, but not expressive of measure and weight. Only the ordinal numbers can be applied to it, but not the cardinal numbers. (Mises 1998, p. 97)

As one can see from the above quote, Mises’s value theory is completely subjective, with the consequence that he would not only refuse the

Marxian labor theory of value but also the welfare economics of a Léon Walras (1834–1910). For Mises, value or utility is something that only the individual attaches to a good. It cannot be measured and therefore interpersonal utility comparisons and concepts like “aggregate welfare” are invalid. On this issue, Mises takes the same line as Czech economist Franz Cuhel (1862–1914) (Rothbard 1988, pp. 19 and 59). The only common denominator of individual preferences and evaluations, through which heterogeneous goods and services can be compared somewhat objectively, is the price system of a free market. However, this is not to be confused with measuring utility in terms of money prices.

From this insight, Mises derives his critique of central planning. In a centrally planned economy, where the means of production are not privately owned and therefore are not sold and bought on the market, there are no market prices for production or capital goods. Consequently, there is no way for the central planners to determine which production processes or which combinations of capital resources, for the production of some desired good, are economically efficient and in line with consumer preferences. In short, economic calculation is impossible under socialism. *Socialism: An Economic and Sociological Analysis*, the relevant book for this topic, is to a large extent built on an earlier article that started the socialist calculation debate, *Economic Calculation in the Socialist Commonwealth*. According to Friedrich August von Hayek, this debate and in particular Mises’s contribution had a remarkable impact on the social scientists and economists of his generation, who predominantly favored socialism over the free market (Hayek 1981).

In *A Critique of Interventionism*, Mises provides us with a very distinctive clarification of another crucial question concerning political economy. If socialism is inherently dysfunctional, what about a middle-of-the-road solution – a mixed economy that is neither a complete free market system nor full-blown socialism? Can we combine the benefits of both systems in a suitable way? Mises’s answer is no. Such a system of interventionism would be inherently unstable. For every problem that the government detects

and attempts to solve through intervention into the economy, it will most of the time not only not solve the problem but also create new ones. After each intervention the government can then either take the initial intervention back or go on to intervene further into the economy. Mises argued that interventionism is a slippery slope and ultimately leads to socialism. The only alternative is provided by a genuine free market system (Bagus 2013). This idea of the self-reinforcing character of interventionism has been picked up by Hayek in his best-selling popular book *The Road to Serfdom* (von Hayek 2005). Hayek does not deny the impact that Mises had on his political philosophy, although some economists and philosophers who see themselves more in line with the Misesian tradition and the Rothbardian interpretation thereof, such as Walter Block, criticized Hayek sharply for his “lukewarm” defense of laissez-faire capitalism (Block 1996).

Although his critique of the state is extensive, Mises would not deny the necessity of the state altogether. As unmistakably explained in *Liberalism*, he assigns a unique task to the state, namely, the enforcement of law and in particular the protection of private property. Mises thereby remains in the tradition of classical liberalism (Hoppe 2013). It was Murray N. Rothbard, certainly Mises’s most influential American student, who would enrich the Misesian analysis of the state with his theory of rational ethics developed in his philosophical treatise *The Ethics of Liberty* (Rothbard 2003) and push it to its ultimate conclusion: the state should be abolished. Rothbard spearheaded the anarcho-capitalistic movement in the United States that today is more vibrant than ever.

When it comes to pure economics, Mises probably made his most important contributions in the area of monetary theory and business cycle theory. In his habilitation thesis, *The Theory of Money and Credit* (von Mises 1912), he elaborates on Menger’s account of the origins of money out of barter trade to solve a challenge that has been laid down to the Austrian economists by Karl Helfferich (1872–1924) in 1903. In his work *Money*, Helfferich correctly pointed out that the “Austrians,” despite their comprehensive

microeconomic analysis of markets and prices for goods and services, had not yet managed to solve the problem of money. Money had been treated separately from the rest of economics in a “macro-box,” independently of utility, value, and relative prices (Rothbard 1988, p. 55). When trying to explain the value of money, one ended up in a circular argument. Money is a special good that is demanded not for consumption but for exchange – in the present or some point in the future. It is demanded because it has an exchange value, but it has its exchange value only because it is demanded. This circular reasoning posed a problem that Mises was able to solve by incorporating the time dimension into this interdependency (Hülsmann 2013).

The demand for money today is determined by the exchange value of money in previous periods. The demand for money in previous periods was determined by its exchange value in still earlier periods, and so the chain of reasoning goes backward in time. Do we end up in an infinite regress? No, because at some point back in time, the money good has been demanded, as any other good, for its value in consumption. At this point, we are back in a barter economy. This is the starting point. In a transition from direct to indirect exchange, in order to overcome the problem of the double coincidence of wants, some goods and eventually one single good will become universally accepted as a medium of exchange. This good will become money. Traditionally, precious metals such as gold and silver have played this role, since they are rare, homogeneous, highly divisible, transportable, and durable. Mises’s explanation, which we call the *Regression Theorem*, “was a remarkable achievement, because for the first time, the micro/macro split that had begun in English classical economics with Ricardo was now healed” (Rothbard 1988, p. 57). Money was incorporated into the rest of economic theory and had no longer to be treated separately. For a more detailed outline and interpretation of Mises’s monetary theory, the interested reader may have a look at *Theory of Money and Fiduciary Media* edited by Guido Hülsmann (2012), an anthology of essays in celebration of the centennial of Mises’s major work.

The next fundamental contribution by Ludwig von Mises is his theory of business cycles that emerged out of his monetary theory. Thinking about the way money evolves on the market according to Menger and Mises, one recognizes that our current monetary system is quite special, in the sense that our money is not backed by any real good. We are living in a fiat money system. Our money is money by government decree. However, this regime has been transformed into what it is today by government intervention out of a gold-backed monetary system, and its mere existence does therefore not disprove the Mengerian-Misesian account. That it is advantageous for any government to possess the monopoly over the production of an unbacked currency is quite obvious. It enables the government to create money out of thin air through credit expansion and to lower interest rates artificially. The Keynesian view holds that this is a necessary political tool for anti-cyclical economic stabilization and therefore the cure of the business cycle which is inherent to free market capitalism. Mises, on the contrary, sees the root cause of the business cycle not in the free market itself but precisely in artificial credit expansion. Mises’s explanation is as follows.

He built his theory out of three preexisting components, the business cycle model of the Currency School, the differentiation between the “natural rate of interest” and the “bank rate of interest” by Swedish economist Knut Wicksell (1898), and the Böhm-Bawerckian capital and interest theory (Rothbard 1988, p. 63; Hülsmann 2007, Chapter 6). Mises argues that pumping money into the economy by expanding credit and lowering interest rates under the “natural” time preference level cause excess malinvestments in capital goods industries.

In Mises’s view, the interest rate is not an arbitrary number that should be interfered with. Instead, it is the price that tends to accommodate the roundaboutness of production processes or investment projects to the available subsistence fund in the economy. Usually, interest rates fall, when consumers save more and thereby increase the subsistence fund. However, in the case of artificial credit expansion, the decrease in interest

rates and the subsequent excess investments are not justified or covered by real savings. Therefore, some of these investments, sooner or later, have to be liquidated, when it turns out that the subsistence fund in the economy is too small to finish them all.

Note that artificial credit expansion is not a purely political phenomenon that can only be brought about by the state. It can and did happen on the market, on behalf private banks. However, it is only through the institutionalization of credit expansion, by establishing a central bank system, that it has reached today's magnitude.

Hayek won the Nobel Memorial Prize in economics in 1974, the year after Mises's death. He received it precisely for his contributions to business cycle theory, that is, the work he did in the 1920s and 1930s as an "ardent Misesian" (Rothbard 1988, p. 112). This decision by the Nobel Prize committee gave a boost to Austrian economics in general and Austrian business cycle theory in particular. According to Rothbard, it marked a "revival of Austrian economics."

The financial crisis of 2007 has attracted more attention to the Austrian explanation of booms and busts. Subsequent to this event, Ron Paul, presidential candidate in the United States, gained increased recognition for his critique of the Federal Reserve System and his call to abolish it. His arguments are essentially backed by Misesian ideas.

Mises's "last great work" and "by far the most neglected" was *Theory and History*. Yet, it "provides the philosophical backstop and elaboration of the philosophy underlying *Human Action*" (Rothbard 1985). He had a lot of opponents concerning his political recommendations, but it was his methodological uniqueness that made him an academic outlier for his whole life. In *Theory and History*, Mises provides the philosophical justification for considering the social sciences, including economics, as a completely different branch than the natural sciences. The subjects of investigation in the social sciences are human beings, with minds, who have preferences and make choices – who have goals and try to attain these goals. They act purposefully and they change their minds constantly. Human action does not follow mechanical and quantifiable

laws like atoms or molecules do in physics. The empirical approach to the social sciences is ignorant of the uniqueness and the individuality of human decisions and the environment in which each decision is made. Human action is not replicable. By pointing out this insight, Mises made the case for methodological dualism. In the natural sciences, the researcher looks at data of repeated identical experiments in which all relevant variables can be controlled to find and isolate causal relationships. In economics, we already know the ultimate cause: humans act to attain their ends. This knowledge is not hypothetical. It is in Mises's words apodictically true and is not subject to empirical falsification – and neither are logical deductions from this primordial fact. Mises has been called unscientific and mystical for calling economics an "a priori" science, in the same way as mathematics is an "a priori" science. He has been criticized for being ignorant of economic history. His rebuttal is contained in *Theory and History*. It is the historicist-positivist-empiricist economist who overlooks the unique character of historical events by trying to draw generalized conclusions from observable data and thereby ignores the single common feature of all economic data: purposefully acting individual human beings. For Mises, it is not history that can provide us with a reliable theory. It is only by means of a theoretical framework that we can make sense out of historical data.

Today, the ideas of Ludwig von Mises and his intellectual followers are promoted more effectively than ever before by the *Ludwig von Mises Institute* in Auburn, Alabama. It was founded in 1982 by Llewellyn H. Rockwell Jr., Burton Blumert, and Murray N. Rothbard. Its website, www.mises.org, makes a large number of books, journal articles, and other writings available for free. It is worth a look for every interested reader. There exist a number of professional journals and periodicals published by the institute, including *The Journal of Libertarian Studies* (1977–2008), *The Review of Austrian Economics* (1987–1998), and *The Quarterly Journal of Austrian Economics* (since 1998).

Today, without formal ties among them, there exist more than 14 Mises Institutes worldwide,

including those in Belgium, Switzerland, Germany, Portugal, Sweden, Finland, Czech Republic, Romania, Poland, Russia, Canada, Brazil, Ecuador, and Japan. There also exist a Spanish Language Institute and a Mises Institute Europe.

Money Laundering

Donato Masciandaro
Department of Economics, Bocconi University,
Milan, Italy

Abstract

Money laundering is any activity aimed to hide the origin and/or the destination of a flow of money in order to reduce the probability of sanctions. In order to describe the economics of money laundering, the starting point is the definition of its microeconomic foundations, which are based on the existence of a rational actor who derives revenues from a criminal activity and from the assumption that his/her expected utility depends on four key elements: expected revenues, laundering costs, likelihood of being caught, and magnitude of the sanction.

The micro basis of the money laundering can explain its macroeconomic effects. Money laundering can function as a multiplier mechanism of the weight of the illegal sector in a given territory or country. In order to prevent and combat the polluting effects of money laundering, an effective regulation has to be designed, based on a correct incentives alignment between the supervisors and the financial intermediaries.

Definition

Money laundering is any activity aimed to hide the origin and/or the destination of a flow of money in order to reduce the probability of sanctions.

Only recently the economic analysis has developed a peculiar focus on the financial issues related to the study of crime, thus far completely absent (Masciandaro 2007; Unger and Van der Linde 2013). In this entry, a simple framework to explain the micro foundations of the money laundering activities in order to analyze its macroeconomic effects on the relationship between the illegal activities and the economic sector as a whole will be offered.

Microeconomics

The emphasis on the study of money laundering has progressively increased, recognizing its potential role in the development of any crime that generates revenues and or in financing a crime. In fact, the conduct of any illegal activity may be subject to a special category of transaction costs, linked to the fact that the use of the relative revenues increases the probability of discovery of the crime and therefore incrimination. The analysis zooms on the economics of concealing illegal sources of revenues, but the same reasoning can be applied in discussing the hidden financing of illegal activities (money dirtying).

However, we should stress that in terms of economic analysis, the financing of illegal activities (money dirtying) is a phenomenon not perfectly equivalent from the recycling of capital (money laundering).

The money dirtying resembles money laundering in some respects and differs from it in others. The objective of the activity is to channel funds of any origin to individuals or groups to enable illegal acts – for example, terrorism – or activities. Again in this case, an organization with such an objective must contend with potential transaction costs, since the financial flows may increase the probability that the financed crime will be discovered, thus leading to incrimination. Therefore, an effective money dirtying action, an activity of concealment designed to separate financial flows from their destination, can minimize the transaction costs.

The main difference between money laundering and money dirtying is in the origin of the

financial flows. While in the money laundering process the concealment regards capitals derived from illegal activity, the illegal actor or organization can use both legal and illegal fund for financing their action.

Money laundering and money dirtying may coexist. A typical example is the financing of terrorism with the proceeds from the production of narcotics. In those specific situations, the importance of the transaction costs is greater, since the need to lower the probability of incrimination concerns both the crimes that generated the financial flows and the crimes for which they are intended. The value of a concealment operation is even more significant.

The definition of money laundering points up its specialness with respect to other illegal or criminal economic activities involving accumulation and/or reinvestment. Now, given that the conduct of any illegal activity may be subject to a special category of transaction costs, linked to the fact that the use of the relative revenues increases the probability of discovery of the crime and therefore incrimination, those transaction costs can be minimized through an effective laundering action, a means of concealment that separates financial flows from their origin.

In other words, whenever a given flow of purchasing power that is potential – since it cannot be used directly for consumption or investment as it is the result of illegal accumulation activity – is transformed into actual purchasing power, money laundering has occurred.

Focusing our attention on the concept of incrimination costs enables us to grasp not only the distinctive nature of this illegal economic activity but also its general features. The definition here adopted maintains basic unity among three aspects that, according to other points of view, represent three different objects of the anti-laundering action: the financial flows (layering), the wealth and goods intended as terminal moments of those flows (integration), and the principal actors, or those who have that wealth and goods at their disposal (placement).

In this general framework of analysis, there will always be an agent who, having committed

a crime that has generated accumulation of illicit proceeds, moves the flows to be laundered, so as to subsequently increase his/her financial assets, by investment in the legal sector or re-accumulation in the illegal sector. The agent can be an individual or a criminal organization.

By criminal organization, we mean a group of individuals and instrumental assets associated for the purpose of exclusively exchanging or producing services and goods of an illicit nature or services and goods of a licit nature with illicit means or of illicit origin.

In general, following the classic intuition à la Becker, it can be claimed that the choices of an economic agent to invest his/her resources in illegal activities – as money laundering is – will depend, *ceteris paribus*, on two peculiar magnitudes, given the possible returns: the probability of being incriminated and the punishment he/she will undergo if found guilty.

Now, to undertake money-laundering activity, the agent possessing liquidity coming from illegal activity will decide whether to perform a further illicit act, in a given economic system – i.e., money laundering – assessing precisely the probability of detection and relative punishment and comparing that with the expected gains, net of the economic costs of this money-laundering activity.

The choice of the agent requires that the crime in question, and the relative production function, be basically autonomous with respect to other forms of crime, those that generated the revenues in the accumulation phase.

Assigning a monetary utility to the crime of money laundering, by giving it a unitary expression, actually summarizes the value of a series of more general services that stimulate the growth of demand for money-laundering services on the part of the agents that accumulate illegal resources. Money laundering, in fact, produces for its users:

1. The economic value, in the strict sense, of minimizing the expected incrimination costs, transforming into purchasing power the liquidity deriving from a wide range of criminal activities (transformation); transformation, in turn, produces two more utilities for the criminal agent.

2. The possibility of increasing his/her rate of penetration in the legal sectors of the economy through the successive phase of investment (pollution).
3. The possibility of increasing the degree to which the criminal actors and organizations are camouflaged in the system as a whole (camouflaging).

Having defined the micro choices in the most general terms possible, we can now investigate the macro effects of money-laundering choices.

Macroeconomics

To define a macro model of the accumulation-laundering-investment process, we focus on the behavior of a general criminal sector that derives its income from a set of illegal activities and that, under certain conditions, must launder the income to invest it. We will highlight the role of money laundering as an overall multiplier of the criminal sector endowment.

Let us assume – as in Masciandaro 1999 and then in Barone and Masciandaro 2011 – that in a given economic system, there is a criminal sector that controls an initial volume of liquid funds ACI , fruit of illegal activities of accumulation. Let us further suppose that, at least for part of those funds, determined on the basis of the optimal microeconomic choices already discussed in the previous pages, there is a need for money laundering. Without separating these funds from their illicit origin, given the expected burden of punishment, they have less value. Money-laundering activity is therefore required.

To underscore the general nature of the analysis, we can claim that the demand for money-laundering services could be expressed – distinguishing the different potential components of a criminal sector according to their primary illegal activity – by organized crime in the strict sense, by white collar crime, or by political corruption crime, also considering the relative crossover and commingling.

Each laundering phase has a cost for the criminal sector, represented by the price of the

money-laundering supply. The price of the money-laundering service, all other conditions being equal, will depend on the costs of the various money-laundering techniques. Let us suppose that in the money-laundering markets, the criminal sector is price taker and that the cost of money-laundering cR is constantly proportional to the amount of the illicit funds; designating the costs with c , both regulatory and technical, we can write:

$$cR = cACI \quad (1)$$

If the first laundering phase is successful, the criminal sector may spend and invest the remaining liquid funds $(1 - c)yACI$ in both legal economic activities (investment) and illicit activities (re-accumulation).

The trend to use specialist money launderers – with their explicit or implicit fees – is increasing. These operators use their expertise to launder criminal proceeds. In general, the professionals may be witting or unwitting accomplice; but in any case, the buildup of the overall procedure represents a cost.

We assume that in general, the money-laundering procedures represent a cost for organized crime, notwithstanding it is well known that the criminal groups can implement legal businesses also for the concealment of their illegal proceeds and these businesses can produce profits. As it will be evident below, the smaller the money-laundering costs will be, the greater the multiplier effect.

The criminal sector will spend part of the laundered liquidity in consumer goods, equal to d , while a second portion will be invested in the legal sectors of the economy, for an amount of f , and then a third portion, equal to q , will be reinvested in illegal markets (giving, of course, $d + f + q = 1$).

On the one side share of illegal funds needs to be spent: minimizing incrimination risks comes at a price; the criminal sector has to pay a price. On the other side, we suppose that a share of dirty money will be reinvested in the illegal market without concealment. For example, in all illicit services, cash is by definition the currency of

choice, running in a closed circuit separate from the legitimate market.

Reinvestment in criminal markets is a distinctive feature of actual organized crime groups, given their tendency toward specialization. Organized crime tends to acquire specialist functions to augment their illegal businesses.

If the criminal sector makes investment choices according to the classical principles of portfolio theory, indicating with $q(r, s)$ the amount of laundered funds reinvested in illegal activities, with r the actual expected return on the illegal re-accumulation, and with s the relative. Finally, we can assume that the re-accumulation of funds in the illegal sector requires their laundering only in part, thus indicating with the positive parameter y the portion of illegal re-accumulation that requires laundered liquidity.

The criminal sector reinvests both clean and dirty money, and then a new flow of illegal liquidity will be created. The illegal revenues will be characterized again by incrimination costs, which will generate a new demand for money-laundering services. It will be therefore equal to:

$$(1 + r)(1 - c)^2 q y^2 ACI \quad (2)$$

The crucial assumption is that both the lawful investment and part of the unlawful re-accumulation require financing with “clean” cash. This assumption can be supported by the presence of rational, informed operators in the supply of services to the criminal sector for the illegal re-accumulation or by rationality of the criminal himself/herself, who wishes to minimize the probability of being discovered.

Repeating infinite times, the demand for money-laundering services, which each time encounter a parallel supply, with the values of the parameters introduced remaining constant, the total amount of financial flows generated by money-laundering activity AFI will be equal to:

$$AFI = \frac{yACI(1 - c)}{1 - yq(1 - c)(1 + r)} = mACI \quad (3)$$

with $0 < c, q, y < 1$.

The flow AFI represents the overall financial endowment generated by the money-laundering activity, and m can be defined as the multiplier of the model. Doing comparative static exercises, it is easy to show that the amount of liquidity laundered will increase as the price of the money-laundering service declines:

$$\frac{\partial AFI}{\partial c} = - \frac{ACI y}{[1 - yq(1 - c)(1 + r)]^2} < 0 \quad (4)$$

Therefore, the more effective the money-laundering action, the greater the cash flows available to the criminal sector for reinvestment, illegal and legal, will be. Money laundering represents the multiplier of the illegal sector.

Regulation

Summing up the key features of money laundering, the micro foundations have been based on the existence of a rational criminal actor or organization, which derives revenues from an illicit or criminal activity. The criminal actor or organization wants to maximize the expected utility of his/her or its illicit proceeds. The expected utility increases with the average return, and it decreases with the costs for laundering, with the probability of being caught, and with the severity of the sanction when being caught.

Further, the macroeconomic effects of money laundering have been captured using a multiplier model. Money laundering triggers a multiplier process, which ends up with higher laundering and higher criminal activities. Money laundering harms the economy. Therefore, it can be useful to design and implement a regulation to prevent and combat the money-laundering phenomena.

On this respect, the starting point has to be to recognize that the banking and financial industry usually play a pivotal role for the development of the criminal sector as a preferential vehicle for money laundering.

The main actors are on the one hand the regulatory agents, who want to combat money

laundering, and on the other hand the financial intermediaries, who can be either honest and compliant or dishonest and noncompliant. Asymmetric information and principal-agent problems are typical for this market. The design of anti-money-laundering regulations must take four aspects into consideration: the difference in information assets between the individual intermediaries and the agency, the non-verifiability of bankers' efforts to comply, the costliness of that effort for the intermediaries, and the non-verifiability of the influence of the effort on the performance of the regulation.

To deal with such difficulties, the best way of analyzing the regulatory issues is to implement a principal-agent methodology, managing the incentive problems that arise at least in a three-layer hierarchy, which includes public authorities, financial institutions, and supervisors. It is possible to show – Dalla Pellegrina and Masciandaro (2009) – that the under asymmetric information, the effectiveness of the regulation depends on three crucial conditions.

First, the participation constraint of the financial institutions requires that the incentive scheme is well balanced, meaning that both rewards and penalties must be defined, in order to minimize the difference between the private costs in implementing a regulatory model and the public gains in collecting useful information against money laundering.

Second, excessive fines per se do not necessarily provide incentives to the financial institutions to improve their action. In particular, given the incentive scheme of the financial institutions, the quality of the supervision can be a good substitute for the severity of punishments: the more effective the (potential) supervisory action in monitoring ex post the money-laundering risk, the more likely the effectiveness of the financial institutions in building up ex ante their monitoring models.

Third, other things being equal, if the cost of supervision depends on its quality, also the efficiency of the supervisory agencies matters. Again, the importance of the quality and the efficiency of supervision can be particularly relevant.
